## Methods

**Object**  
 toToString  
 toLocaleString  
 valueOf  
 hasOwnProperty  
 isPrototypeOf  
 propertyIsEnumerable

**String**  
 charAt  
 charCodeAt  
 fromCharCode  
 concat  
 indexOf  
 lastIndexOf  
 localeCompare  
 match  
 replace  
 search  
 slice  
 split  
 substring  
 substr  
 toLowerCase  
 toUpperCase  
 toLocaleLowerCase  
 toLocaleUpperCase

**RegEx**  
 test  
 match  
 exec

**Array**  
 concat  
 join  
 push  
 pop  
 reverse  
 shift  
 slice  
 sort  
 splice  
 unshift

**Number**  
 toFixed  
 toExponential  
 toPrecision

**Date**  
 parse  
 toDateString  
 toTimeString  
 getDate  
 getDay  
 getFullYear  
 getHours  
 getMilliseconds  
 getMinutes  
 getMonth  
 getSeconds  
 getTime  
 getTimezoneOffset  
 getYear  
 setDate  
 setHours  
 setMilliseconds  
 setMinutes  
 setMonth  
 setSeconds  
 setYear  
 toLocaleTimeString

# JavaScript

## XMLHttpRequest

**Safari, Mozilla, Opera:**  
`var req = new XMLHttpRequest();`  
**Internet Explorer:**  
`var req = new ActiveXObject("Microsoft.XMLHTTP");`

## XMLHttpRequest Object Methods

abort()  
 getAllResponseHeaders()  
 getResponseHeader(header)  
 open(method, URL)  
 send(body)  
 setRequestHeader(header, value)

## XMLHttpRequest Object Properties

onreadystatechange  
 readyState  
 responseText  
 responseXML  
 status  
 statusText

## XMLHttpRequest readyState Values

0 Uninitiated  
 1 Loading  
 2 Loaded  
 3 Interactive  
 4 Complete

## JAVASCRIPT IN HTML

**External JavaScript File**  
`<script type="text/javascript"  
 src="javascript.js"></script>`  
**Inline JavaScript**  
`<!--  
 // JavaScript Here  
 -->`  
`</script>`

## Functions

<b>Window</b>	<b>Built In</b>
alert	eval
blur	parseInt
clearTimeout	parseFloat
close	isNaN
focus	isFinite
open	decodeURI
print	decodeURIComponent
setTimeout	encodeURI
	encodeURIComponent
	escape
	unescape

## REGULAR EXPRESSIONS - FORMAT

Regular expressions in JavaScript take the form:  
`var RegEx = /pattern/modifiers;`

## REGULAR EXPRESSIONS - MODIFIERS

/g Global matching  
 /i Case insensitive  
 /s Single line mode  
 /m Multi line mode

## REGULAR EXPRESSIONS - PATTERNS

^ Start of string  
 \$ End of string  
 . Any single character  
 (a|b) a or b  
 (...) Group section  
 [abc] Item in range (a or b or c)  
 [^abc] Not in range (not a or b or c)  
 a? Zero or one of a  
 a\* Zero or more of a  
 a+ One or more of a  
 a{3} Exactly 3 of a  
 a{3,} 3 or more of a  
 a{3,6} Between 3 and 6 of a  
 !(pattern) "Not" prefix. Apply rule when URL does not match pattern.

## EVENT HANDLERS

onAbort	onMouseDown
onBlur	onMouseMove
onChange	onMouseOut
onClick	onMouseOver
onDoubleClick	onMouseUp
onDragDrop	onMove
onError	onReset
onFocus	onResize
onKeyDown	onSelect
onKeyPress	onSubmit
onKeyUp	onUnload
onLoad	

## FUNCTIONS AND METHODS

A method is a type of function, associated with an object. A normal function is not associated with an object.

Available free from  
[www.ILoveJackDaniels.com](http://www.ILoveJackDaniels.com)

## DOM Methods

**Document**  
 clear  
 createDocument  
 createDocumentFragment  
 createElement  
 createEvent  
 createEventObject  
 createRange  
 createTextNode  
 getElementsByTagName  
 getElementById  
 write

**Node**  
 addEventListener  
 appendChild  
 attachEvent  
 cloneNode  
 createTextRange  
 detachEvent  
 dispatchEvent  
 fireEvent  
 getAttributeNS  
 getAttributeNode  
 hasChildNodes  
 hasAttribute  
 hasAttributes  
 insertBefore  
 removeChild  
 removeEventListener  
 replaceChild  
 scrollIntoView

**Form**  
 submit

**DOM Collections**  
 item

**Range**  
 collapse  
 createContextualFragment  
 moveEnd  
 moveStart  
 parentElement  
 select  
 setStartBefore

**Style**  
 getPropertyValue  
 setProperty

**Event**  
 initEvent  
 preventDefault  
 stopPropagation

**XMLSerializer**  
 serializeToString

**XMLHTTP**  
 open  
 send

**XMLElement**  
 loadXML

**DOMParser**  
 parseFromString

Regular Expressions Syntax		Pattern Modifiers (cont)		JavaScript Arrays	
^	Start of string	x *	Allow comments and whitespace in pattern	concat()	slice()
\$	End of string	e *	Evaluate replacement	join()	sort()
.	Any single character	U *	Ungreedy pattern	length	splice()
(a b)	a or b	* PCRE modifier		pop()	toSource()
(...)	Group section			push()	toString()
[abc]	In range (a, b or c)			reverse()	unshift()
[^abc]	Not in range			shift()	valueOf()
\s	White space				
a?	Zero or one of a				
a*	Zero or more of a				
a*?	Zero or more, ungreedy				
a+	One or more of a				
a+?	One or more, ungreedy				
a{3}	Exactly 3 of a				
a{3,}	3 or more of a				
a{,6}	Up to 6 of a				
a{3,6}	3 to 6 of a				
a{3,6}?	3 to 6 of a, ungreedy				
\	Escape character				
[:punct:]	Any punctuation symbol				
[:space:]	Any space character				
[:blank:]	Space or tab				
There's an excellent regular expression tester at: <a href="http://regexpal.com/">http://regexpal.com/</a>					
Pattern Modifiers		JavaScript RegExp Object		JavaScript Numbers and Maths	
g	Global match	compile()	lastParen	abs()	min()
i *	Case-insensitive	exec()	leftContext	acos()	NEGATIVE_INFINITY
m *	Multiple lines	global	multiline	asin()	PI
s *	Treat string as single line	ignoreCase	rightContext	atan()	POSITIVE_INFINITY
		input	source	atan2()	pow()
		lastIndex	test()	ceil()	random()
		lastMatch		cos()	round()
JavaScript Event Handlers		JavaScript Event Handlers		JavaScript Event Handlers	
		onabort	onmousedown	E	sin()
		onblur	onmousemove	exp()	sqrt()
		onchange	onmouseout	floor()	SQRT1_2
		onclick	onmouseover	LN10	SQRT2
		ondblclick	onmouseup	LN2	tan()
		ondragdrop	onmove	log()	toSource()
		onerror	onreset	LOG10E	toExponential()
		onfocus	onresize	LOG2E	toFixed()
		onkeydown	onselect	max()	toPrecision()
		onkeypress	onsubmit	MAX_VALUE	toString()
		onkeyup	onunload	MIN_VALUE	valueOf()
		onload		NaN	

JavaScript Booleans		JavaScript Strings	
toSource()	valueOf()	charAt()	slice()
toString()		charCodeAt()	split() x
JavaScript Dates		concat()	
Date()	setMonth()	fromCharCode()	substr()
getDate()	setFullYear()	indexOf()	toLowerCase()
getDay()	setHours()	lastIndexOf()	toUpperCase()
getMonth	setMinutes()	length	toLocaleLowerCase()
getFullYear	setSeconds()	localeCompare()	toLocaleUpperCase()
getYear	setMilliseconds()	match() x	toSource()
getHours	setTime()	replace() x	valueOf()
getMinutes	setUTCDate()	search() x	
getSeconds	setUTCDay()	String object methods with an x support regular expressions.	
getMilliseconds	setUTCMonth()		
getTime	setUTCFullYear()		
getTimezoneOffset()	setUTCHours()	decodeURI()	isNaN()
getUTCDate()	setUTCMinutes()	decodeURIComponent()	Number()
getUTCDay()	setUTCSeconds()	encodeURI()	parseFloat()
getUTCMonth()	setUTCMilliseconds()	encodeURIComponent()	parseInt()
getUTCFullYear()	toSource()	escape()	String()
getUTCHours()	toString()	eval()	unescape()
getUTCMinutes()	toGMTString()	isFinite()	
getUTCSeconds()	toUTCString()		
getUTCMilliseconds()	toLocaleString()		
parse()	UTC()		
setDate()	valueOf()

The screenshot shows a development environment with two main windows. On the left is a Sublime Text window titled "classes.html" containing the following JavaScript code:

```
<!DOCTYPE html>
<html>
<head>
    <title>Advance JS</title>
    <script>

        class hello{
            message(){
                console.log("Hello Everyone");
            }
            sorry(){
                console.log("Sorry Everyone");
            }
        }

        let a = new hello();

        a.message();
        a.sorry();

    </script>
</head>
<body>
```

On the right is a browser developer tools window titled "Advance JS" showing the "Console" tab. It displays the following log entries:

Message	Source
Hello Everyone	classes.html:9
Sorry Everyone	classes.html:12

## JS Class & Object in PHP

```
class hello{  
    message(){  
        console.log("Hello Everyone");  
    }  
}  
  
let a = new hello();  
a.message();
```

## JS Type of Methods :

### Constructor

```
constructor(){  
    console.log("hello");  
}
```

### Prototype

```
message(){  
    console.log("hello")  
}
```

### Static

```
static name(){  
    console.log("hello")  
}
```

## JS Type of Methods :

### Constructor

```
constructor(){
    console.log("hello");
}
```

### Prototype

```
message(){
    console.log("hello")
}
```

### Static

```
static name(){
    console.log("hello")
}
```

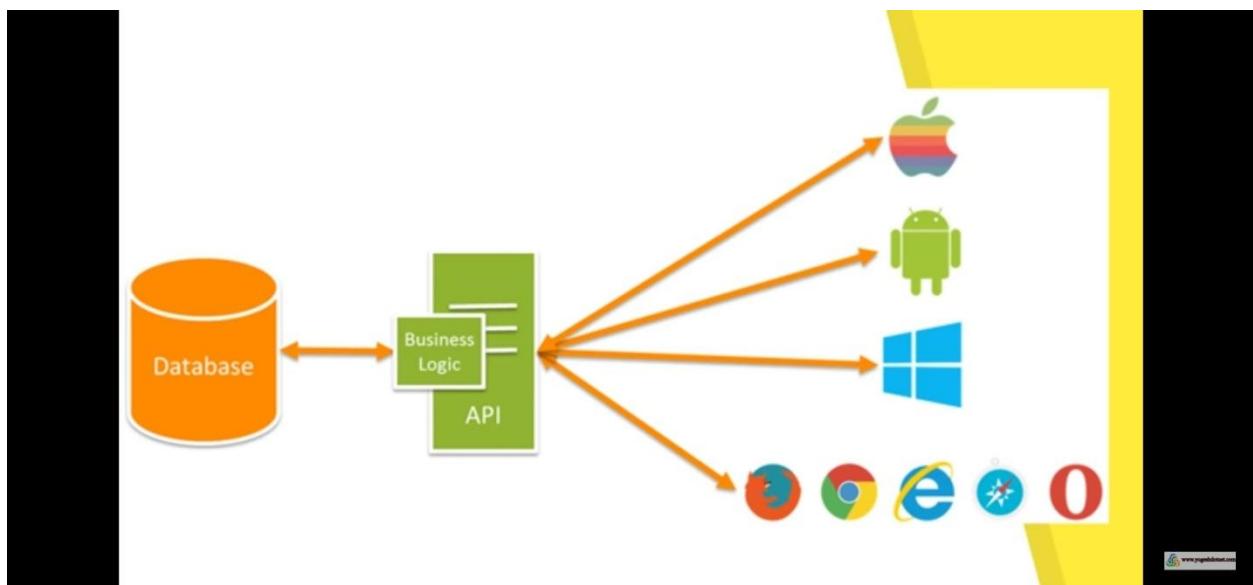

## Pillar of OOPS

- ▶ **Data Abstraction**(**Data hide**)
- ▶ **Inheritance.** (**Reusability**)
- ▶ **Polymorphism.** (**Object to take many forms**)
- ▶ **Encapsulation.** (**Data hide**)

# REST API

CRUD Operations:-

Operation	HTTP Methods	Description
Create	POST	Creating/Posting/Inserting Data
Read	GET	Reading/Getting/Retrieving Data
Update	PUT, PATCH	Updating Data Complete Update - PUT Partial Update - PATCH
Delete	DELETE	Deleting Data

# JSON.stringify()

Transforms a JavaScript object into a JSON string.

# JSON.parse()

Takes a JSON string and transforms it into a JavaScript object.

```
> const student = {  
  name:"Alex",  
  age:20,  
  email:"alex@email.com"  
};  
  
> const studentStr = JSON.stringify(student);  
  
> console.log(studentStr);  
  
{"name":"Alex", "age":20, "email":"alex@email.com"}  
  
> const jsObject = JSON.parse(studentStr);  
  
> console.log(jsObject);  
  
Object { age: 20, email: "alex@email.com", name: "Alex" }  
  
> |
```

## Data Format of JSON & XML

**JSON**

```
{"students": [  
  {"name": "Ram", "age": "23", "city": "Agra"},  
  {"name": "Sonam", "age": "28", "city": "Delhi"}]
```

**XML**

```
<students>  
  <student>  
    <name>Ram</name> <age>23</age> <city>Agra</city>  
  </student>  
  <student>  
    <name>Sonam</name> <age>28</age> <city>Delhi</city>  
  </student>  
</students>
```

 [Yahoo Baba](http://www.yahooibaba.net) [www.yahooibaba.net](http://www.yahooibaba.net)

## Difference Between JSON & XML

### JSON

- 1) JavaScript Object Notation
- 2) Text Based Format
- 3) Light Weight
- 4) Does not support comments and namespaces

### XML

- 1) Extensible Markup Language
- 2) Markup Language
- 3) Heavier
- 4) Supports comments and namespaces

## Javascript Object Literals Vs JSON

### JavaScript Object

```
var person = { firstName : "Yahoo", lastName : "Baba" };
```

### JSON

```
var person = { "firstName" : "Yahoo", "lastName" : "Baba" };
```

## Javascript Object Literals Vs JSON

### JavaScript Object

```
var person = { firstName : "Yahoo", lastName : "Baba" };
alert(person.firstName + " " + person.lastName);
```

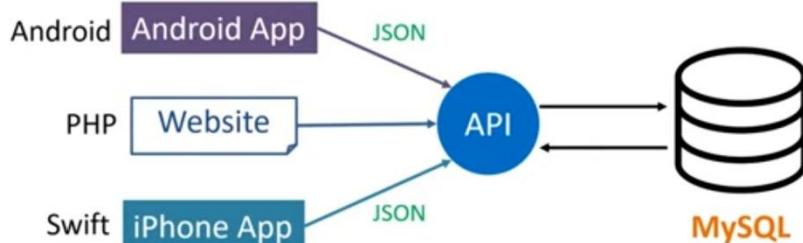

### JSON

```
var person = { "firstName" : "Yahoo", "lastName" : "Baba" };
alert(person.firstName + " " + person.lastName);
```

## What is API ?

### Application Program Interface

## Advantages of JSON :

- Human Readable Format
- Language Independent
- Supports all Popular Programming languages
- Easy to organised and access
- It is light-weight

Can not use it for transfer video, audio, images or any other binary information.

## What we learn in next videos ?

- How to read JSON data in Website Front End
- How to produce JSON data in PHP
- How to work with APIs

## What is Object ?

▶▶▶

0 1 2 3  
var a = ["Ram", "Kumar", 18 , "India"];

var a = {

firstName : "Ram" ,  
lastName : "Kumar" ,  
age : 18 ,  
country : "India"

};

## How to Target DOM Object :

▶▶▶

- Id → document.getElementById(id)
- Class Name → document.getElementsByClassName(name)
- Tag Name → document.getElementsByTagName(name)

## Other DOM Targeting Methods :

- document.links
- document.forms
- document.doctype
- document.URL
- document.baseURI
- document.domain

- document
- document.all
- document.documentElement
- document.head
- document.title
- document.body
- document.images
- document.anchors

## DOM Get Methods :

- innerText
- innerHTML
- getAttribute
- getAttributeNode
- Attributes

## DOM Set Methods :

- innerText
- innerHTML
- setAttribute
- Attribute
- removeAttribute

Yahoo  
Baba

The screenshot shows a dual-pane interface. On the left, an Atom code editor displays the file 'variables.html' with the following content:

```
<!DOCTYPE html>
<html>
<head>
<title>JavaScript</title>
<script>
    var firstname = "Yahoo";
    firstname = "Baba";

    document.write(firstname);
</script>
</head>
<body>
</body>
</html>
```

On the right, a browser window with developer tools open shows the console tab. The console output is 'Baba'. Below the browser window, the DevTools Network tab shows a single request for 'variables.html' with a status of 'Live reload enabled.'

## Difference between Variable Types:

Var

Let

Const

```
var x = "Hello";
```

```
var x = "World";
```

```
x = "WoW";
```

```
let x = "Hello";
```

```
let x = "World";
```

```
x = "WoW";
```

```
const x = "Hello";
```

```
const x = "World";
```

```
x = "WoW";
```

## Different Type of Assignment Operators :

Operator	Example	Same As
=	$x = y$	$x = y$
+=	$x += y$	$x = x + y$
-=	$x -= y$	$x = x - y$
*=	$x *= y$	$x = x * y$
/=	$x /= y$	$x = x / y$
%=	$x \%= y$	$x = x \% y$
**=	$x **= y$	$x = x ** y$

## Different Type of Data Types :

var x = "Hello World"; → String  
var x = 25; → Number  
var x = true; → Boolean  
var x = ["HTML","CSS","JS"]; → Array  
var x = {first:"Jane", last:"Doe"}; → Object  
var x = null; → Null  
var x; → Undefined

## Different Type of Comparison Operators :

Operator	Description
==	equal to
===	equal value and equal type
!=	not equal
!==	not equal value or not equal type
>	greater than
<	less than
>=	greater than or equal to
<=	less than or equal to

## JavaScript Basic Events

- Click
- Double Click
- Right Click
- Mouse Hover
- Mouse Out
- Mouse Down
- Mouse Up
- Key Press
- Key Up
- Load
- Unload
- Resize
- Scroll

## For Loop Syntax in JavaScript :

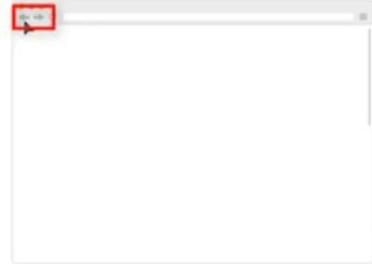

Initialization   Condition   Increment / Decrement

```
for(var a = 1; a <= 10; a++){
    document.write("Yahoo Baba");
}
```

## Browser Object Model

- Get Width & Height of Browser Window
- Open & Close Browser Window
- Move & Resize Browser Window
- Scroll to Browser Window
- Get URL, Hostname, Protocol of Browser Window
- Get History of Browser Window

Yahoo  
Baba

## JavaScript Math Methods :

Yahoo  
Baba

- ceil(x)
- floor(x)
- round(x)
- trunc(x)
- max(x, y, z, ..., n)
- min(x, y, z, ..., n)
- sqrt(x)
- cbrt(x)
- pow(x, y)
- random()
- abs(x)
- PI

## JavaScript Math Methods :

- `toDateString()`
- `getDate()`
- `getFullYear()`
- `getMonth()`
- `getDay()`
- `getHours()`
- `getMinutes()`
- `getSeconds()`
- `getMilliseconds()`
- `setDate()`
- `setFullYear()`
- `setHours()`
- `setMilliseconds()`
- `setMinutes()`
- `setMonth()`
- `setSeconds()`

## JavaScript Number Methods :

- `number()`
- `parseInt()`
- `parseFloat()`
- `isFinite()`
- `isInteger()`
- `toFixed(x)`
- `toPrecision(x)`

## JavaScript Array Methods :

- sort()
- reverse()
- pop()
- push()
- shift()
- unshift()
- concat()
- join()
- slice()
- splice()
- isArray()
- indexOf()
- lastIndexOf()
- entries()
- every()
- filter()
- find()
- findIndex()
- includes()
- some()
- forEach()
- toString()
- valueOf()
- fill()

## For / in Loop :

```
var a = {  
    firstName : "Ram" ,  
    lastName : "Kumar" ,  
    age : 18 ,  
    country : "India"  
};
```

```
for(var i in a){  
    Statement  
}
```

## Array – Map() Function :

```
var a = [1 , 3 , 5 , 8 , 10];  
a.map(function(){  
    Statement  
});
```

## How to Target DOM Object :

- Id → `document.getElementById(id)`
- Class Name → `document.getElementsByClassName(name)`
- Tag Name → `document.getElementsByTagName(name)`

## Other DOM Targeting Methods :

- document
- document.all
- document.documentElement
- document.head
- document.title
- document.body
- document.images
- document.anchors
- document.links
- document.forms
- document.doctype
- document.URL
- document.baseURI
- document.domain

## JavaScript Basic Events

- Click (onclick)
- Double Click (ondblclick)
- Right Click (oncontextmenu)
- Mouse Hover (onmouseenter)
- Mouse Out (onmouseout)
- Mouse Down (onmousedown)
- Mouse Up (onmouseup)
- Key Press (onkeypress)
- Key Up (onkeyup)
- Load (onload)
- Unload (onunload)
- Resize (onresize)
- Scroll (onscroll)

 Why use jQuery ?

- Short Selectors
- Variety of Animation Functions
- Easy DOM Manipulation
- Easy CSS Styling
- Easy DOM Traversing
- Simple Ajax Code

Yahoo Baba

## Short Selectors Example :

```
document.getElementsByClassName('classname')  
$('.classname')
```

```
document.getElementById('idname')  
$('#idname')
```

```
document.getElementsByTagName('tagname')  
$('tagname')
```

① ② ③ ④ ⑤ ⑥

Yahoo  
Baba

### JavaScript

```
<script>  
    var a = document.getElementById("idName").innerHTML;  
    console.log(a);  
</script>
```

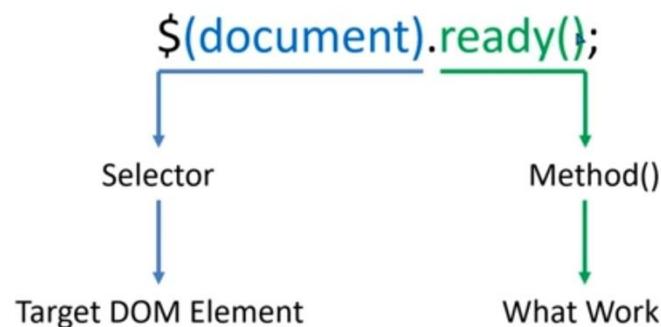

### jQuery

```
<script>  
    $(document).ready(function(){  
        Further jQuery Code  
    });  
</script>
```

Yahoo  
Baba

## jQuery Basic Syntax

① ② ③ ④ ⑤ ⑥

Yahoo  
Baba

## Another Method to start jQuery Code :

```
$(document).ready(function(){
```

```
});
```

---

```
$(function(){
```

```
});
```

Yahoo  
Baba

## Targeting DOM Element with ID, Class & Tag

Select by Id : `$("#idName")`

Select by Class Name : `$(".className")`

Select by Tag Name : `$("tagName")` → `$("p")`

Yahoo  
Baba

## Advance Selectors

`$("*")`

`$("p:first")`

`$("ul li")`

`$("p:last")`

`$(".abc , .xyz")`

`$("li:even")`

`$("h1, div, p")`

`$("li:odd")`

Yahoo  
Baba

## Get Methods

- `text()`
- `html()`
- `attr()`
- `val()`

5:49 ④

VoIP LTE1 .11 VoIP LTE2 4G .11 69%

```
Syntax
$(document).ready(function(){
  $(".demo").click(function(){
    $(this).hide(200);
  });
});
$(function(){
  // Short Document Ready
});

Each
$(".demo").each(function() {
  document.write($(this).text() + "\n"); // output
});

Trigger
$("a#mylink").trigger("click"); // triggers event or

noConflict
var jq = $.noConflict();           // avoid conflict
jq(document).ready(function(){
  jq("#demo").text("Hello World!");
});

## JS Promise Syntax

```
let prom = new Promise(function(resolve, reject){  
  if(condition){  
    resolve();  
  } else{  
    reject();  
  }  
});
```

```
let onfulfilment = (result) => {  
  console.log(result);  
}  
  
let onRejection = (error) => {  
  console.log(error);  
}
```

## JS Fetch() Syntax

```
fetch();
```

```
fetch(file / URL);
```

Promise

```
fetch(file / URL).then();
```

Promise

```
fetch(file / URL).then(function(response){  
    return response.data;  
});
```

text()

json()

## JS Different type of Variable :

ES6

Var

Let

ES6

Const

```
var x = "Hello";
```

```
var x = "World";
```

```
x = "WoW";
```

```
let x = "Hello";
```

```
let x = "World"; ✗
```

```
x = "WoW";
```

```
const x = "Hello";
```

```
const x = "World"; ✗
```

```
x = "WoW"; ✗
```

## JS What is Fetch() Method ?

AJAX

JavaScript ES6

jQuery

```
$ajax();  
$.get();  
$.post();
```

Fetch()

- Insert
- Update
- Read
- Delete

JavaScript

XMLHttpRequest

## JS What is Modules ?

USE

Variables

Functions

Classes

File1.js

File2.js

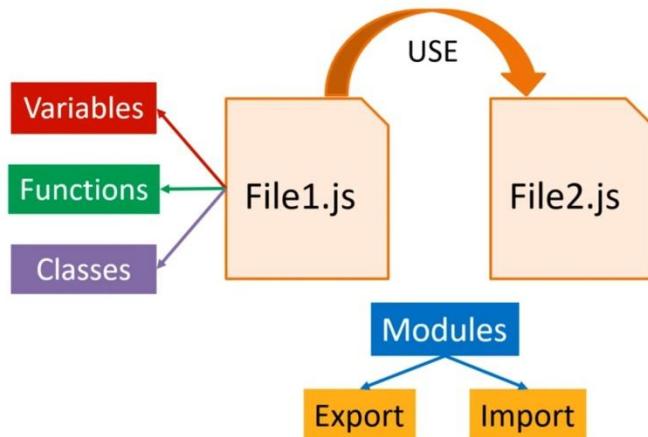

Modules

Yahoo Baba

[www.yahooibaba.net](http://www.yahooibaba.net)

Yahoo  
Baba

## JS What is Modules ?

Yahoo Baba

[www.yahooibaba.net](http://www.yahooibaba.net)

Yahoo  
Baba

## JS How to work with Modules ?

File1.js

```
export let name = "Yahoo Baba";
export function hello{
}
export class user{
}
```

File2.js

```
import { name } from './File1.js'
import { hello } from './File1.js'
import { user } from './File1.js'
console.log(name);
hello();
let a = new user();
```

HTML File

```
<script type="module" src="./File2.js"></script>
```

Yahoo Baba

[www.yahooibaba.net](http://www.yahooibaba.net)

Yahoo  
Baba

## JS JavaScript : Data Types

```
var x = "Hello World"; → String  
var x = 25; → Number  
var x = true; → Boolean  
var x = ["HTML","CSS","JS"]; → Array  
var x = {first:"Jane", last:"Doe"}; → Object  
var x = null; → Null  
var x; → Undefined
```

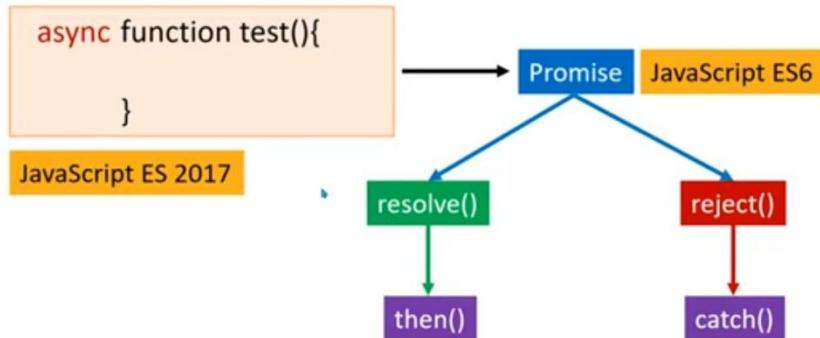

## JS Symbol Data Type

```
var x = Symbol();  
  
var x = Symbol("Hello"); → Unique Value  
  
var y = Symbol("Hello");  
  
console.log(x === y) → False
```

## JS JavaScript : Generators

```
function *test() {  
    Pause ←———— yield "First";  
    yield "Second";  
    yield "Third";  
}  
  
let g = test();  
g.next(); → First  
  
g.next();  
  
g.next();
```

## JS Async Function

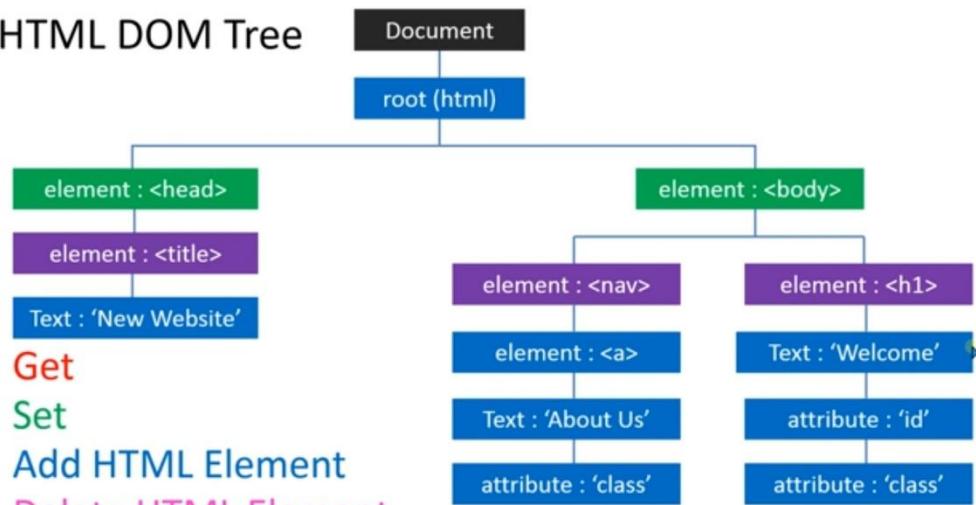

## JS Await Method

```
async function test(){
    console.log("A");
    await console.log("B");
    console.log("C");
}

test();
console.log("D");
console.log("E");
```

## HTML DOM Tree

- innerHTML
- getAttribute
- getAttributeNode
- Attributes

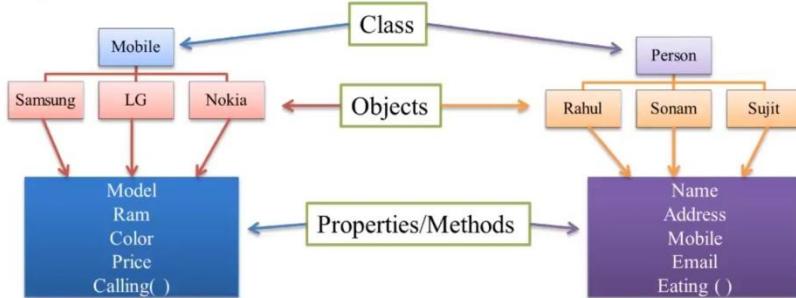

## DOM Set Methods :

- innerText
- innerHTML
- setAttribute
- Attribute
- removeAttribute

# Class

A specific category can be defined as class.

Example:-

www.geekyshows.com

## Defining a Class

We define class in JavaScripts using custom constructor.

```
var Mobile = function(model_no, sprice) {  
    this.model = model_no;  
    this.color = 'white';  
    this.price = 3000;  
    this.sp = sprice;  
    this.sellingprice = function() {  
        return (this.price + this.sp);  
    };  
};  
var samsung = new Mobile('Galaxy', 2000);
```

www.geekyshows.com

# Defining a Class

We define class in JavaScripts using custom constructor.

```
var Mobile = function(model_no, sprice) {  
    this.model = model_no;  
    this.color = 'white';  
    this.price = 3000;  
    this.sp = sprice;  
    this.sellingprice = function() {  
        return (this.price + this.sp);  
    };  
};  
  
var samsung = new Mobile('Galaxy', 2000);  
var nokia = new Mobile('3310', 1000);  
↳
```

[www.geekyshows.com](http://www.geekyshows.com)

# Defining a Class

We define class in JavaScripts using custom constructor.

```
var Mobile = function(model_no, sprice) {  
    this.model = model_no;  
    this.color = 'white';  
    this.price = 3000;  
    this.sp = sprice;  
    this.sellingprice = function() {  
        return (this.price + this.sp);  
    };  
};  
  
var samsung = new Mobile('Galaxy', 2000);  
var nokia = new Mobile('3310', 1000);  
↳
```

**ES6 Class**

```
class Mobile {  
    constructor () {  
        this.model = 'Galaxy';  
    }  
    show() { return this.model +  
              "Price 3000";  
    }  
}  
var nokia = new Mobile();
```

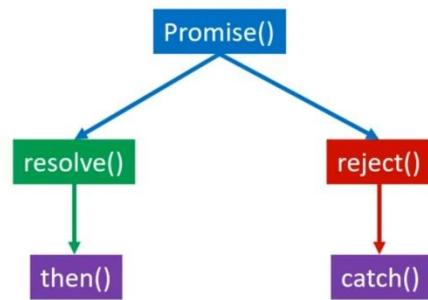

[www.geekyshows.com](http://www.geekyshows.com)

A screenshot of Notepad++ showing a JavaScript file named 'D:\yob\es6\5.html'. The code defines a function 'add' that takes an array of numbers, initializes a sum to 0, iterates through the array using a for loop, and logs the sum to the console. The code is as follows:

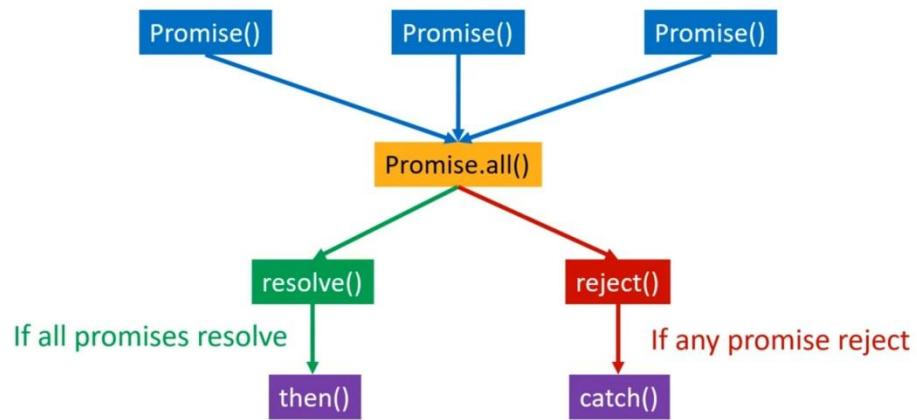

```
<script>
function add(...x) {
    let sum=0;
    for(i=0;i<x.length;i++) {
        sum=sum+x[i];
    }
    console.log(sum);
}
add(10,20,30,40,50);
</script>
```

The Notepad++ interface includes a status bar at the bottom displaying file information like length, lines, and position.

## JS | What is Promise ?

## JS | What is Promise.all() ?

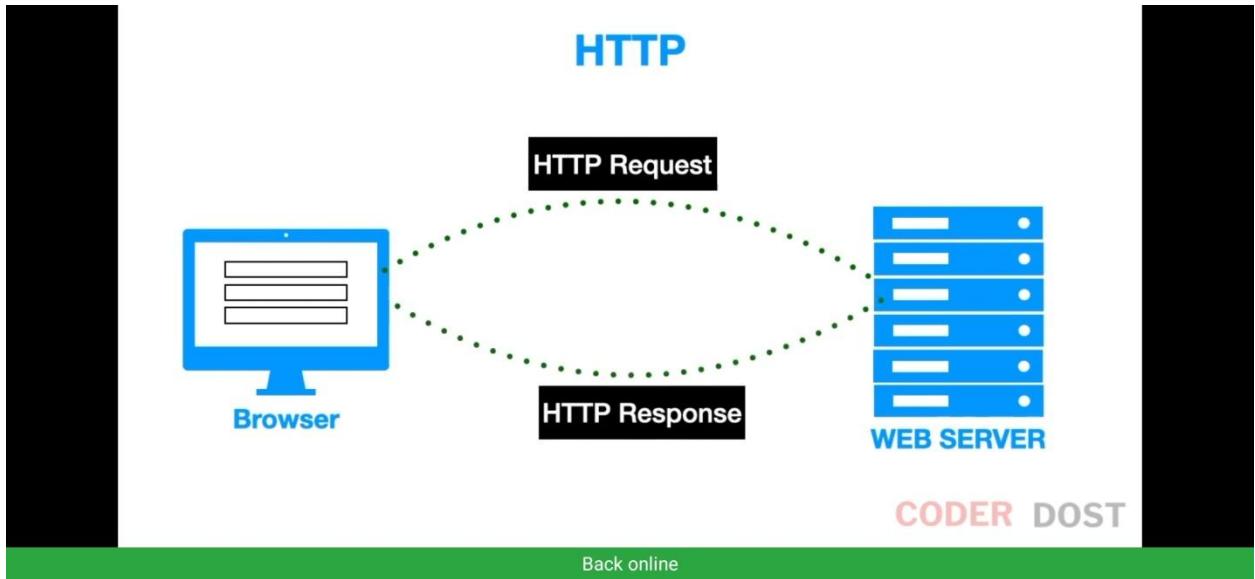

Yahoo Baba

[www.yahooibaba.net](http://www.yahooibaba.net)

## Promise : .then() & .catch()

```
const p = new Promise(function(resolve, reject){  
})  
p.then(function(data){  
})  
→ ) .catch(function(data){  
})
```

CODER DOST

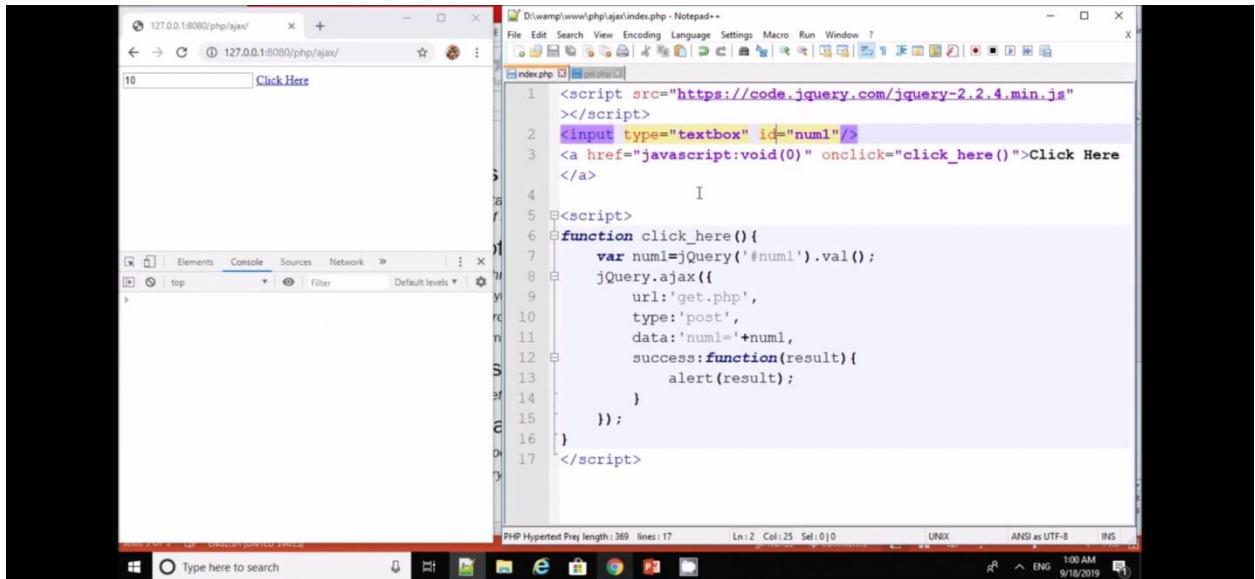

## Recursion in Function

It is the process in which a function calls itself again and again to perform any repetitive task.

### For Example

```
function fact(a)
{
    If(a==1)
        return 1;
    else
        return a*fact(a-1);
}
```

The screenshot shows a Windows desktop environment. In the center is a Notepad++ window titled "D:\wamp\www\php\ajax\index.php - Notepad++". The code in the editor is:

```
1 <script src="https://code.jquery.com/jquery-2.2.4.min.js">
2 </script>
3 <input type="textbox" id="num1"/>
4 <a href="javascript:void(0)" onclick="click_here()">Click Here
5 </a>
6 <script>
7   function click_here(){
8     var num1=$('#num1').val();
9     jQuery.ajax({
10       url:'get.php',
11       type:'post',
12       data:'num1='+num1,
13       success:function(result){
14         alert(result);
15       }
16     });
17 </script>
```

Below the Notepad++ window, the taskbar is visible with various icons. The status bar at the bottom of the screen displays "PHP Hypertext Preprocessor length: 369 lines: 17" and "Ln: 2 Col: 25 Sel: 0 | 0 UNIX ANSI as UTF-8 INS".

## Callback Functions

```
var calc = function(fx,a,b){
    return fx(a,b);
}
```

```
var sum = function(x,y){
    return a+b;
}
```

```
calc(sum,4,5)
```

CODER DOST

The screenshot shows a browser's developer tools interface. On the left, there is a code editor window titled "JS app.js" containing the following JavaScript code:

```
1  function sum(a,b){  
2  |    return a+b;  
3  }  
4  
5  function calc(fx,a,b){  
6  |    return fx(a,b);  
7  }  
8  
9  console.log(calc(sum,4,5));
```

On the right, there is a "Console" tab showing the output of the code execution. The output is:

```
9  
Live reload enabled. (index):38  
>
```

A watermark "CODER DOST" is visible at the bottom right of the screenshot.

The screenshot shows a browser's developer tools interface. On the left, there is a code editor window titled "JS app.js" containing the following JavaScript code:

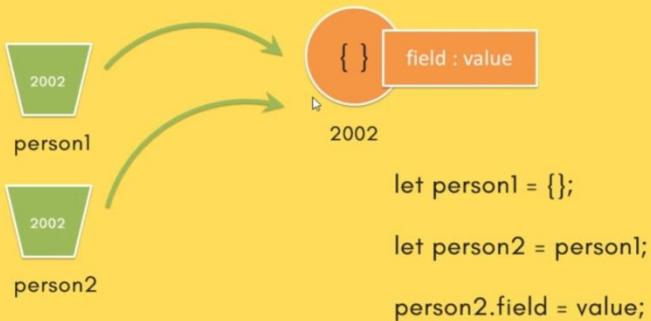

```
1  function sum(a,b){  
2  |    return a+b;  
3  }  
4  function diff(a,b){  
5  |    return a-b;  
6  }  
7  
8  function calc(fx,a,b){  
9  |    return fx(a,b);  
10 }  
11  
12  console.log(calc(diff,4,5));
```

On the right, there is a "Console" tab showing the output of the code execution. The output is:

```
-1  
Live reload enabled. (index):38  
>
```

A watermark "CODER DOST" is visible at the bottom right of the screenshot.

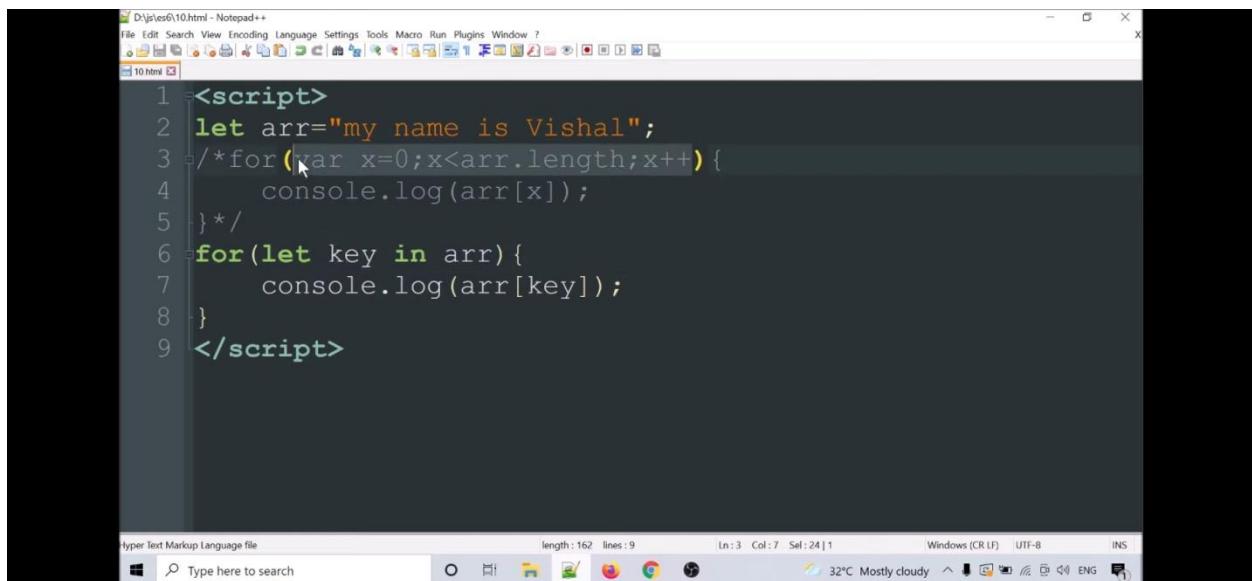

# REFERENCE TYPES

CHEEZYCODE

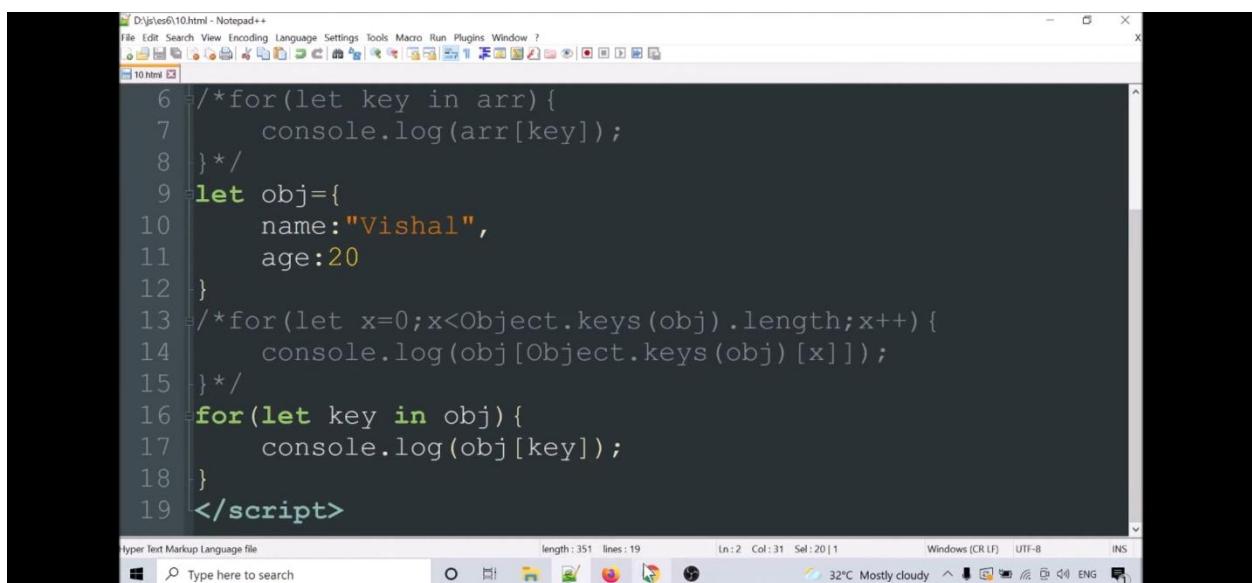

A screenshot of Sublime Text showing a file named `function.html`. The code is a simple JavaScript function that adds two numbers and prints the result to the console.

```
<script type="text/javascript">
var stored = sum(10, 20);
document.write("The sum of two no. is "+stored+"<br>");
function sum(a , b){
    var add = a + b ;
    return add;
}
</script>
```

### **1. Encapsulation: -**

Encapsulation means wrapping up data and member function (Method) together into a single unit i.e. class.

### **2. Abstraction: -**

Abstraction is the process of showing only essential/necessary features of an entity/object to the outside world and hide the other irrelevant information. For example to open your TV we only have a power button, It is not required to understand how infra-red waves are getting generated in TV remote control.

### **3. Inheritance: -**

Inheritance allows a class (subclass) to acquire the properties and behavior of another class (super-class). It helps to reuse, customize and enhance the existing code. So it helps to write a code accurately and reduce the development time.

4. Polymorphism:-

So polymorphism means "many forms". A subclass can define its own unique behavior and still share the same functionalities or behavior of its parent/base class.

```
class square(){
    area()
}

Var S1 = new square();
S1->area();
```

```
class circle(){
    area()
}

Var C1 = new circle();
C1->area();
```

        for(let x of score){
            console.log(x);
        }
    </script>
</body>
</html>
```

A screenshot of Microsoft Word showing a document titled JavaScript Type Casting. The document contains text explaining type casting and its two types: implicit and explicit. It also includes examples of implicit type casting.

Converting one type of data value to another type is called as type casting.

There are **two** types of type casting:

- Implicit type casting (Coercion): Done by JavaScript Engine
- Explicit type casting (Conversion): Done by programmers

**Implicit type casting:**

If required JavaScript engine automatically converts one type of value to another type.  
This is known as implicit type casting.

**Ex:**

```
document.write(2+ 4.3); // 6.3
document.write("2" + 2 ); // "22"
document.write(2 + "2"); // "22"
```

This screenshot shows a Visual Studio Code window with a dark theme. The file being edited is 'index.html'. The code is identical to the one in Sublime Text, demonstrating the 'for...of' loop. The interface includes a sidebar with file navigation icons and a status bar at the bottom.

The `forEach()` method calls a function once for each element in an array, in order.

# forEach() Method

Syntax: `arr.forEach(callback(currentValue [, index [, array]])[, thisArg])`

Argument	Description
<code>currentValue</code>	Required. The value of the current element
<code>index</code>	Optional. The array index of the current element
<code>arr</code>	Optional. The array object the current element belongs to

In programming languages we often say “An object is an instance of a class”.

This means that, using a class, I can create many objects and they all share methods and properties.

Since objects can be enhanced, there are many ways to create objects sharing methods and properties. But we want the simplest one.

## Bind `this`

For methods in React, the `this` keyword should represent the component that owns the method.

That is why you should use arrow functions. With arrow functions, `this` will always represent the object that defined the arrow function.

# Why Arrow Functions?

In class components, the `this` keyword is not defined by default, so with regular functions the `this` keyword represents the object that called the method, which can be the global window object, a HTML button, or whatever.

Read more about binding `this` in our [React ES6 'What About this?'](#) chapter.

If you *must* use regular functions instead of arrow functions you have to bind `this` to the component instance using the `bind()` method:

# bind() Method

by this method, we can bind an object to a common function, so that the function gives different result when its need.

```
<script>
    function Employee(firstName,lastName)
    {
        this.firstName=firstName;
        this.lastName=lastName;
    }

    Employee.prototype.company="Javatpoint"

    var employee1=new Employee("Martin","Roy");
    var employee2=new Employee("Duke", "William");
    document.writeln(employee1.firstName+" "+employee1.lastName+" "+employee1.company+"
    r>");
    document.writeln(employee2.firstName+" "+employee2.lastName+" "+employee2.company);
</script>
```

Let's see an example to add a new property to the constructor function.

```
<script>
    function Employee(firstName,lastName)
    {
        this.firstName=firstName;
        this.lastName=lastName;
    }

    Employee.prototype.company="Javatpoint"

    var employee1=new Employee("Martin","Roy");
    var employee2=new Employee("Duke", "William");
    document.writeln(employee1.firstName+" "+employee1.lastName+" "+employee1.company+"<b>" +
    "<r>");
    document.writeln(employee2.firstName+" "+employee2.lastName+" "+employee2.company);
</script>
```

The screenshot shows a Visual Studio Code interface with two tabs: `index.html` and `index.js`. The `index.js` tab contains the following code:

```
function Student(firstName, lastName, subject) {
    this.firstName = firstName;
    this.lastName = lastName;
    this.subject = subject;
    this.greet = function(){
        console.log(`${this.firstName} ${this.lastName}`);
    }
}

let student1 = new Student("John", "Doe", "CS");
student1.greet();

function Employee(firstName, lastName, department) {
    this.firstName = firstName;
    this.lastName = lastName;
    this.department = department;
    this.greet = function(){
        console.log(`${this.firstName} ${this.lastName}`);
    }
}

let emp1 = new Employee("Jason", "Smith");
emp1.greet();
```

To the right, a browser window displays the output of the console logs:

John Doe  
Jason Smith

CHEEZYCODE

```
const person = {
  firstName:"John",
  lastName: "Doe",
  fullName: function () {
    return this.firstName + " " + this.lastName;
  }
}

console.log( person.fullName() ); // John Doe
```

JS

```
const person = {
  fullName: function() {
    return this.firstName + " " + this.lastName;
  }
}

const person1 = {
  firstName:"John",
  lastName: "Doe"
}
const person2 = {
  firstName:"Mary",
  lastName: "Doe"
}

console.log( person.fullName.call(person1) ); // John Doe
console.log( person.fullName.call(person2) ); // Mary Doe
```

JS

```
const obj = { name: "John" };

let greeting = function(a,b){
    return `${a} ${this.name}. ${b}`;
};

console.log( greeting.call(obj, "Hello", "How are you?") );
// returns: Hello John. How are you?
```

JS

```
const obj = { name: "John" };

let greeting = function(a,b){
    return `${a} ${this.name}. ${b}`;
};

console.log( greeting.apply(obj, ["Hello", "How are you?"]) );
// returns: Hello John. How are you?
```

JS

```
const obj = { name: "John" };

let greeting = function(a,b){
    return `${a} ${this.name}. ${b}`;
}

let bound = greeting.bind(obj);

console.log( bound("Hello", "How are you?") );
// returns: Hello John. How are you?
```

## Array – `findIndex()` Function :

```
var ages = [10 , 23 , 19 , 20];
var adultAge = 18;
ages >= adultAge
```

**findIndex(Function Name)**

`findIndex()` method returns the index of the first element in an array that pass a test

## Array – find() Function :

```
var ages = [10 , 23 , 19 , 20];  
var adultAge = 18;  
ages >= adultAge
```

### find(Function Name)

find() method returns the value of the first element in an array that pass a test

The screenshot shows a development environment with two windows. On the left, the Atom code editor displays a file named 'map.html' containing the following JavaScript code:

```
<!DOCTYPE html>  
<html>  
<head>  
  <title>JavaScript</title>  
  <script>  
    var ary = [11,4,9,16];  
  
    var b = ary.map(test);  
    document.write(b);  
  
    function test(x){  
      return x * 10;  
    }  
  </script>  
</head>  
<body>
```

On the right, a browser window titled 'JavaScript' shows the output of the code: "110,40,90,160". A small 'Yahoo Baba' watermark is visible in the bottom right corner of the browser window.

## Access Modifiers

	Class Itself	Outside Class	Derived Class
Public	✓	✓	✓
Protected	✓	✗	✓
Private	✓	✗	✗

## Namespace

First.php

```
namespace first;  
class test{  
}
```

Second.php

```
namespace second;  
class test{  
}
```

Third.php

```
require First.php;  
require second.php;
```

```
$obj = new first\test();
```

## Web notes

Class is a blue print of object.

memory is allocated for an object by Constructor.

No need of define variable in constructor.

Constructor function is a same as class.

Constructor is a method which is use to initialize object state.

this keyword ka use kewal object ya constructor function ke under hota hai

## History of JavaScript

- JavaScript is a scripting language that enables you to create dynamically updating content, control multimedia, animate images etc.
- Written by Brendan Eich in 1995.
- ECMAScript or ES released in 1997
- ES2 & ES3 released in 1998, 1999 resp.
- ES5 was released in 2009
- ES6 ( or ES2015 ) was released in 2015  
Anything greater than ES5 is called ESNext or ES2015+

14

## Prerequisites

- JavaScript
- ES6
- JSX
- Babel
- Webpack
- Node
- PHP

15

## Why do we use ESNext, JSX, Babel & Webpack?

- ESNext makes for simpler code that is easier to read and write.
- Convert ESNext & JSX syntax to code browser can understand
- Using transformation tools help in optimizing our code for widest variety of browsers.
- Organize your code into smaller modules and then bundle them together using Webpack into a single download

16

## Why do we use ESNext, JSX, Babel & Webpack?

- Both webpack and Babel are tools written in JavaScript and run using Node.js (node)
- Node.js is a runtime environment for JavaScript outside of a browser
- node allows you to run JavaScript code on the command-line..

Yahoo Baba

The image shows a screenshot of a computer screen. On the left is a code editor window titled "array-modify.html" containing the following HTML and JavaScript code:

```
<!DOCTYPE html>
<html>
<head>
<title>JavaScript</title>
<script>
var a = ["Harry", 18, "Male", "BCA"];
</script>
</head>
<body>
</body>
</html>
```

On the right is a browser window titled "JavaScript" showing the output of the script: "Harry 18 Male BCA".

Diagram illustrating array modification:

**Modify Array Element**

```
var a = ["Harry", 18, "BCA"];
var a[1] = 19;
```

**Remove Array Element**

```
var a = ["Harry", 18, "BCA"];
delete a[1];
```

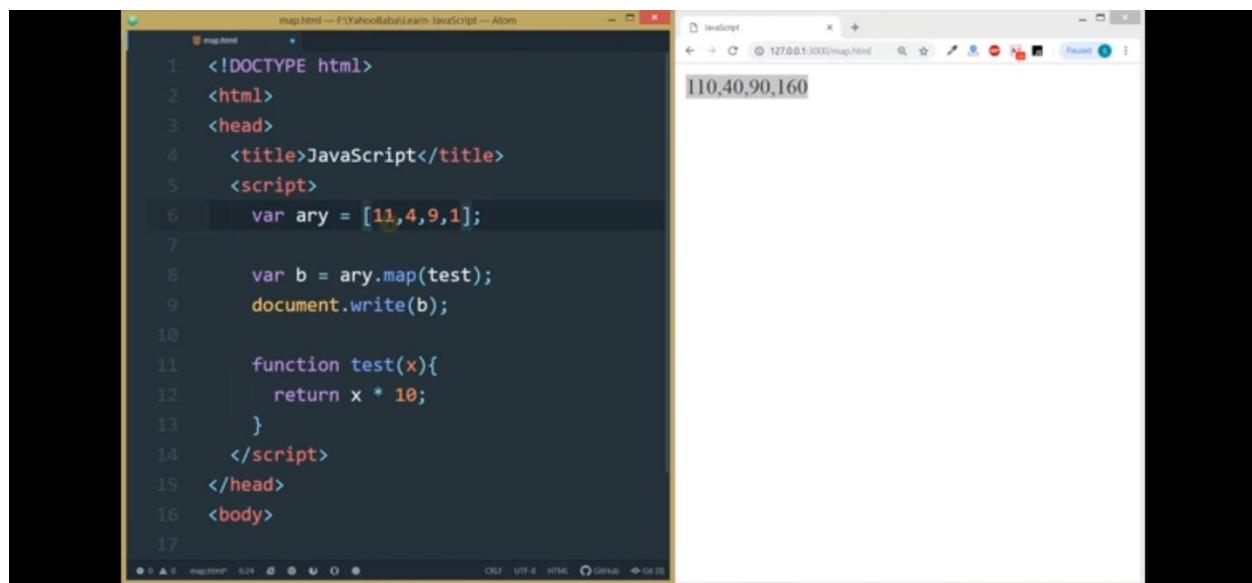

Diagram illustrating the use of the **Map()** function on an array:

**Array – Map() Function :**

```
var a = [1, 3, 5, 8, 10];
a.map(function(){
  Statement
});
```

## Array – Map() Function :

```
var a = [1 , 3 , 5 , 8 , 10];  
a.map(function(){  
    Statement  
});
```

The screenshot shows a dual-pane interface. On the left, an Atom code editor displays the file 'map.html' with the following code:

```
<!DOCTYPE html>  
<html>  
<head>  
<title>JavaScript</title>  
<script>  
    var ary = [11,4,9,1];  
  
    var b = ary.map(test);  
    document.write(b);  
  
    function test(x){  
        return x * 10;  
    }  
</script>  
</head>  
<body>
```

On the right, a browser window titled 'JavaScript' shows the output of the code: '110,40,90,160'.

The screenshot shows a dual-monitor setup. On the left monitor, an Atom code editor window titled "map.html" displays the following JavaScript code:

```
4 <title>JavaScript</title>
5 <script>
6   var ary = [
7     {fname : "Yahoo" , lname : "Baba"},
8     {fname : "Rahul" , lname : "Kumar"},
9     {fname : "Karan" , lname : "Sharma},
10    ];
11
12  var b = ary.map(test);
13  document.write(b);
14
15  function test(x){
16    return x.fname + " " + x.lname;
17  }
18 </script>
19 <head>
20 </head>
```

On the right monitor, a Microsoft Edge browser window titled "JavaScript" shows the output of the code: "Yahoo Baba,Rahul Kumar,Karan Sharma".

The screenshot shows a dual-monitor setup. On the left monitor, an Atom code editor window titled "array-methods.html" displays the following HTML and JavaScript code:

```
1 <!DOCTYPE html>
2 <html>
3   <head>
4     <title>JavaScript</title>
5     <script>
6       var a = ["Sanjay","Aman","Rehman"];
7       document.write(a + "<br><br>");
8       var b = Array.isArray(a);
9       document.write(b + "<br><br>");
10    </script>
11   </head>
12   <body>
13
14   </body>
15 </html>
16
```

On the right monitor, a Microsoft Edge browser window titled "JavaScript" shows the output of the code: "Sanjay,Aman,Rehman" followed by "true".

The screenshot shows two windows side-by-side. On the left is the Atom code editor with a file named 'array-methods.html'. The code contains a script that checks if a variable 'a' is an array. If it is, it writes 'This is an Array' to the page; if not, it writes 'This is not an Array'. The variable 'a' is set to the string 'Rahul'. On the right is a browser window showing the result of running the script, which outputs 'Rahul' followed by 'This is not an Array'.

```
<head>
<title>JavaScript</title>
<script>
//var a = ["Sanjay", "Aman", "Rehman"];
var a = "Rahul";
document.write(a + "<br><br>");

if(Array.isArray(a) == "true"){
    document.write("This is an Array");
} else{
    document.write("This is not an Array");
}

</script>
</head>
<body>
</body>
```

## Array – filter() Function :

```
var ages = [10 , 23 , 9 , 20];
var adultAge = 18;
ages >= adultAge —> [23 , 20]
```

**filter(Function Name)**

filter() method creates an array filled with all array elements that pass a test

The image shows a screenshot of a computer desktop. On the left, there is an Atom code editor window titled "array-methods.html". The code inside is:

```
<!DOCTYPE html>
<html>
<head>
    <title>JavaScript</title>
    <script>
        var ages = [10,12,19,20];
        document.write(ages + "<br><br>");

        var b = ages.filter(checkAdult);
        document.write(b + "<br><br>");

        function checkAdult(age){
            return age >= 18;
        }
    </script>
</head>
<body>
```

On the right, there is a browser window titled "JavaScript" with the URL "127.0.0.1:3000/array-m...". The page displays the output of the script:

10,12,19,20  
19,20

## Array – Join() Function :

var a = ["Aman", "Rehman", "Karan"];

Aman – Rehman – Karan

join()

The screenshot shows a code editor window for the file "array-methods.html". The code uses the `includes` method to check if the string "Aman" is present in the array `a`. The browser output window shows the result as "true".

```
<!DOCTYPE html>
<html>
<head>
    <title>JavaScript</title>
    <script>
        var a = ["Sanjay", "Aman", "Rehman", "Rahul"];
        document.write(a + "<br><br>");

        var b = a.includes("Aman");
        document.write(b + "<br><br>");

    </script>
</head>
<body>

</body>
</html>
```

The screenshot shows a code editor window for the file "array-methods.html". The code uses the `every` method with a custom function `checkAdult` to check if all ages in the array are 18 or older. The browser output window shows the result as "false" because there are ages below 18 in the array.

```
<!DOCTYPE html>
<html>
<head>
    <title>JavaScript</title>
    <script>
        var ages = [10, 13, 15, 2];
        document.write(ages + "<br><br>");

        var b = ages.every(checkAdult);
        document.write(b + "<br><br>");

        function checkAdult(age){
            return age >= 18;
        }
    </script>
</head>
<body>

</body>
</html>
```

## Array – indexOf() Function :

0            1            2            3

var a = ["Sanjay", "Aman", "Rehman", "Aman"];

Aman → 1

indexOf("Search item", Start)

The image shows a dual-pane view. On the left, an Atom code editor displays the file 'array-methods.html' with the following JavaScript code:

```
<!DOCTYPE html>
<html>
<head>
    <title>JavaScript</title>
    <script>
        var a = ["Sanjay", "Aman", "Rehman"];
        var b = a.concat("Rahul", "Karan");
        document.write(b);
    </script>
</head>
<body>
</body>
</html>
```

On the right, a Microsoft Edge browser window shows the output of the code: "Sanjay,Aman,Rehman,Rahul,Karan".

The screenshot shows a Windows desktop environment. On the left, there is a code editor window titled "array-methods.html" in Atom. The code is a simple HTML file with a script that concatenates two arrays and prints the result to the console. On the right, there is a web browser window titled "JavaScript" showing the output of the code: "Sanjay,Aman,Rehman,Rahul,Karan". The browser's address bar shows the URL "127.0.0.1:3000/array-me...". In the bottom right corner of the screen, there is a small "Yahoo Baba" logo.

```
<!DOCTYPE html>
<html>
<head>
<title>JavaScript</title>
<script>
var a = ["Sanjay", "Aman", "Rehman"];
var b = ["Rahul", "Karan"];
var c = a.concat(b);
document.write(c);
</script>
</head>
<body>
</body>
</html>
```

The screenshot shows a web page with a yellow sidebar on the left containing a "JS" logo. The main content area has a white background and features a blue header "Converting an Arrays to Strings". Below the header, there is a list item with a blue circular icon followed by text: "The JavaScript method `toString()` converts an array to a string of (comma separated) array values. JavaScript automatically converts an array to a comma separated string when a primitive value is expected." At the bottom right of the content area, there is a watermark-like text "Activate Windows Go to Settings to activate Windows."

## Converting an Arrays to Strings

- The JavaScript method `toString()` converts an array to a string of (comma separated) array values. JavaScript automatically converts an array to a comma separated string when a primitive value is expected.

Activate Windows  
Go to Settings to activate Windows.

```
97 <script>
98 // array.reduce(function(total, currentValue,
  currentIndex, arr), initialValue)
99 let array = [200,100,200,500];
100 var sum = 0;
101 array.forEach(function(item){
102   sum+=item;
103 })|
104 console.log(sum);
105 </script>
106 </body>
107 </html>
```

<dsc />

## JavaScript Math Methods :

- ceil(x)
- floor(x)
- round(x)
- trunc(x)
- max(x, y, z, ..., n)
- min(x, y, z, ..., n)
- sqrt(x)
- cbrt(x)
- pow(x, y)
- random()
- abs(x)
- PI

## JavaScript Number Methods :

- number()
- parseInt()
- parseFloat()
- isFinite()
- isInteger()
- toFixed(x)
- toPrecision(x)

## JavaScript Math Methods :

- toDateString()
- getDate()
- getFullYear()
- getMonth()
- getDay()
- getHours()
- getMinutes()
- getSeconds()
- getMilliseconds()
- setDate()
- setFullYear()

- innerHTML
- getAttribute
- getAttributeNode
- Attributes

Yahoo  
Baba

The screenshot shows the Atom code editor with two files open: 'dom.html' and 'dom-main.js'. The 'dom.html' file contains the following HTML code:

```
<html>
<head>
    <title>Yahoo Baba</title>
</head>
<body>
    <div id="content">
        <p>Aenean lacinia bibendum nulla sed consectetur.</p>
        <ul>
            <li>Home</li>
            <li>About Us</li>
            <li>Gallery</li>
            <li>Contact Us</li>
        </ul>
    </div>
</body>
</html>
```

The 'dom-main.js' file contains the following JavaScript code:

```
var element;

element = document.getElementById("content").innerText;

console.log(element);
```

To the right of the code editor is a browser window showing the rendered HTML. The page has a red header with the text 'Yahoo Baba'. Below it is a purple navigation bar with the following menu items:

- Home
- About Us
- Gallery
- Contact Us

The main content area displays the text 'Aenean lacinia bibendum nulla sed consectetur.' followed by a list of menu items.

A screenshot of the Atom code editor interface. On the left, there are two tabs: 'dom.html' and 'dom-main.js'. The 'dom-main.js' tab contains the following JavaScript code:

```
1 var element;
2
3 element = document.getElementById("content").innerHTML;
4
5 console.log(element);
6
```

The code editor has a status bar at the bottom with icons for file operations, encoding (UTF-8), GitHub integration, and Git status.

On the right, a browser window displays a web page with a red header, a purple sidebar containing a navigation menu with items like 'Home', 'About Us', 'Gallery', and 'Contact Us', and a light blue footer. A developer tools panel is open, showing the DOM tree. The 'Elements' tab shows the 'content' element with its innerHTML. The 'Memory' tab shows memory usage. The 'Sources' tab lists 'dom-main.js:5' and 'dom.html:76'. The status bar at the bottom of the browser window also shows file operations, encoding, GitHub, and Git status.

A screenshot of the Atom code editor interface, similar to the one above. The 'dom-main.js' tab now contains this JavaScript code:

```
1 ement;
2
3 t = document.getElementById("header").getAttribute("class");
4
5 e.log(element);
6
```

The code editor status bar shows file operations, encoding (UTF-8), GitHub, and Git status.

The browser window on the right shows the same web page structure. The developer tools panel is still open, showing the DOM tree. The 'Elements' tab shows the 'header' element with its class attribute. The 'Memory' tab shows memory usage. The 'Sources' tab lists 'dom-main.js:5' and 'dom.html:76'. The status bar at the bottom of the browser window shows file operations, encoding, GitHub, and Git status.

A screenshot of the Atom code editor showing a file named 'dom-main.js'. The code is as follows:

```
1  element;
2
3  element = document.getElementById("header").attributes[2].name;
4
5  console.log(element);
6
```

The code highlights the line `element = document.getElementById("header").attributes[2].name;` with a yellow background. To the right of the editor is a browser window displaying a simple website with a red header, a purple sidebar menu containing 'Home', 'About Us', 'Gallery', and 'Contact Us', and some placeholder text.

## DOM Set Methods :

- `innerText`
- `innerHTML`
- `setAttribute`
- `Attribute`
- `removeAttribute`

## New DOM Targeting Methods :

- **querySelector** → `document.querySelector(CSS Selector)`
- **querySelectorAll** → `document.querySelectorAll(CSS Selector)`

Yahoo  
Baba

JavaScript DOM querySelector & querySelectorAll Tutorial in Hindi

```
1 var element;
2
3 document.querySelector("#header").innerHTML = "<h1>Wow</h1>";
4
5 element = document.querySelector("#header").getAttribute("class");
6
7 console.log(element);
8
```

The screenshot shows a code editor window titled "dom-main.js" in the "F:\YahooBaba\Learn-JavaScript" directory using the Atom editor. The code demonstrates how to change the innerHTML of an element and retrieve its class attribute. To the right of the editor is a browser developer tools panel showing the DOM tree. The header element has been modified to contain the text "Wow". The browser's status bar at the bottom indicates the video is at 3:57 / 9:45.

The screenshot shows the Atom code editor with the following details:

- File Tabs:** dom.html (inactive), dom-main.js (active).
- Code Editor:** The file contains the following JavaScript code:

```
1 var element;
2
3 document.querySelector("#header").innerHTML = "<h1>Wow</h1>";
4
5 element = document.querySelectorAll(".list");
6 console.log(element);
7
```

A code action menu is open over the line `element = document.querySelectorAll(".list");` with the following options:
  - Select an action
  - Extract to function in global scope
  - Extract to constant in enclosing scope
- Right Panel:** Shows a preview of the DOM structure and some placeholder text.
- Status Bar:** Shows file path (F:\YahooBaba\Learn-JavaScript — Atom), line numbers (1, 5), and file statistics (2 hidden).
- Bottom Status Bar:** Shows file path (dom.html:74), file name (dom-main.js), line number (5:43), character position (1, 5), encoding (UTF-8), language (JavaScript), GitHub icon, and Git status (0).

The screenshot shows the Atom code editor with two tabs: 'dom.html' and 'dom-main.js'. The 'dom-main.js' tab contains the following code:

```
1 var element;
2
3 document.querySelector("#header").innerHTML = "<h1>Wow</h1>";
4
5 element = document.querySelectorAll(".list")[1].innerHTML;
6 console.log(element);
7
```

The browser preview on the right shows a header with the text 'Wow' and a list below it.

Atom status bar: js\dom-main.js<sup>8</sup> 5:58

Atom bottom right: Yahoo Baba

## DOM CSS Styling Methods :

- **Style**
- **className**
- **classList**

Yahoo  
Baba

The screenshot shows the Atom code editor interface. On the left, the code file `dom-main.js` contains the following JavaScript code:

```
1 var element;
2
3 document.querySelector("#header").style.backgroundColor = "tan";
4 document.querySelector("#header").style.color = "blue";
5 element = document.querySelector("#header").style.color;
6
7 console.log(element);
8
```

On the right, the `main.css` file shows the corresponding CSS rules:

```
header main.css:42
{
  padding: 30px 0
  0 20px;
  margin: 0; Yahoo
  Baba
```

The browser preview window shows a vertical bar with different colored segments (tan, blue, purple, grey) representing the applied styles.

A screenshot of the Atom code editor. The main pane displays the following JavaScript code:

```
1 var element;
2
3 document.querySelector("#header").className = "abc";
4
5 element = document.querySelector("#header").className;
6
7 console.log(element);
8
```

The code editor interface includes tabs for 'dom.html', 'dom-main.js' (which is the active tab), 'color.css', and 'main.css'. A status bar at the bottom shows file statistics (0 0 ▲ 0 js\dom-main.js 5:54) and system information (CRLF, UTF-8, JavaScript, GitHub, Git (0)). On the right side, there's a vertical toolbar with icons for file operations and a color palette.

## JavaScript Basic Events

- Click (onclick)
- Double Click (ondblclick)
- Right Click (oncontextmenu)
- Mouse Hover (onmouseenter)
- Mouse Out (onmouseout)
- Mouse Down (onmousedown)
- Mouse Up (onmouseup)
- Key Press (onkeypress)
- Key Up (onkeyup)
- Load (onload)
- Unload (onunload)
- Resize (onresize)
- Scroll (onscroll)

## HTML Event Attributes :

```
<button onClick="abc()"></button>
```

```
<img src.." onmouseenter="xyz()">
```

YahOO  
Baba

## Assign Events Using the HTML DOM :

```
document.getElementById(Id).onclick = functionName;
```

YahOO  
Baba

The screenshot shows the Atom code editor with two tabs: 'dom.html' and 'dom-main.js'. The 'dom-main.js' tab contains the following code:

```
1 var element;
2
3
4 document.getElementById("header").onclick = abc;
5
6 function abc(){
7     document.getElementById("header").style.background = "green";
8 }
9
10
11 //console.log(element);
12
13
```

The code defines a variable 'element', sets an onclick event on the header element to call the 'abc' function, and defines the 'abc' function to change the header's background color to green. A comment at the bottom indicates the intention to log 'element' to the console.

## DOM addEventListener() Method :

document.getElementById(Id). **addEventListener("click", functionName);**

## DOM addEventListener() Method :

```
document.getElementById(Id). addEventListener("click", functionName);
```

```
document.getElementById(Id). addEventListener("click", function(){  
    Statement  
});
```

Yahoo  
Baba

The screenshot shows the Atom code editor with two tabs: 'dom.html' and 'dom-main.js'. The code in 'dom-main.js' is as follows:

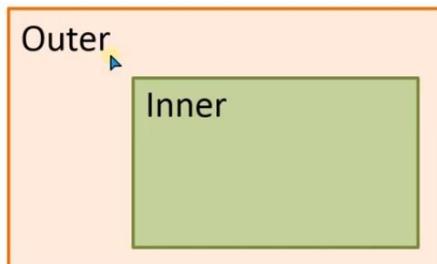

```
var element;  
  
document.getElementById("header").addEventListener("mouseenter",abc);  
document.getElementById("header").addEventListener("click",function(){  
    document.getElementById("header").style.border = "10px solid red";  
});  
  
function abc(){  
    document.getElementById("header").style.background = "green";  
}  
  
//console.log(element);
```

To the right of the editor is a browser window showing a header bar with a green background and a red border. The browser status bar at the bottom right says 'a@copyright 2018. Yahoo Baba'.

```
1 var element;
2
3
4 document.getElementById("header").addEventListener("click",abc);
5 document.getElementById("header").addEventListener("click",function(){
6     this.style.border = "10px solid red";
7 });
8
9 function abc(){
10     document.getElementById("header").style.background = "green";
11 }
12
13
14
15 //console.log(element);
16
```

## UseCapture:

`addEventListener(event, function, useCapture);`

True

False

usecapture.js — P:\YahooBaba\Learn-JavaScript — Atom

### JavaScript addEventListener Method Tutorial in Hindi / Urdu

```
1
2 document.querySelector("#inner").addEventListener('click',function(){
3     alert('Inner Div');
4 },true);
5
6 document.querySelector("#outer").addEventListener('click',function(){
7     alert('Outer Div');
8 },true)|①
9
```

12:53

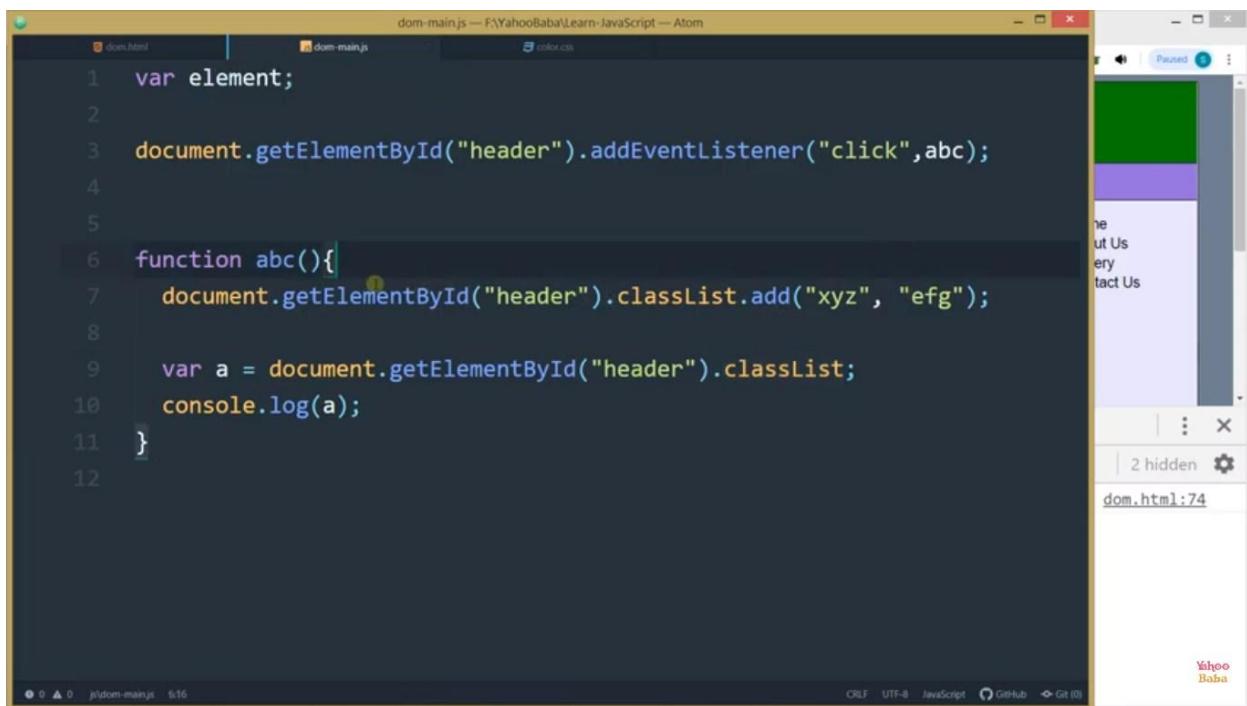

Yahoo Baba

0 Capture 13:08 / 18:04 CRLF UTF-8 JavaScript GitHub Git (0)

## DOM removeEventListener() Method :

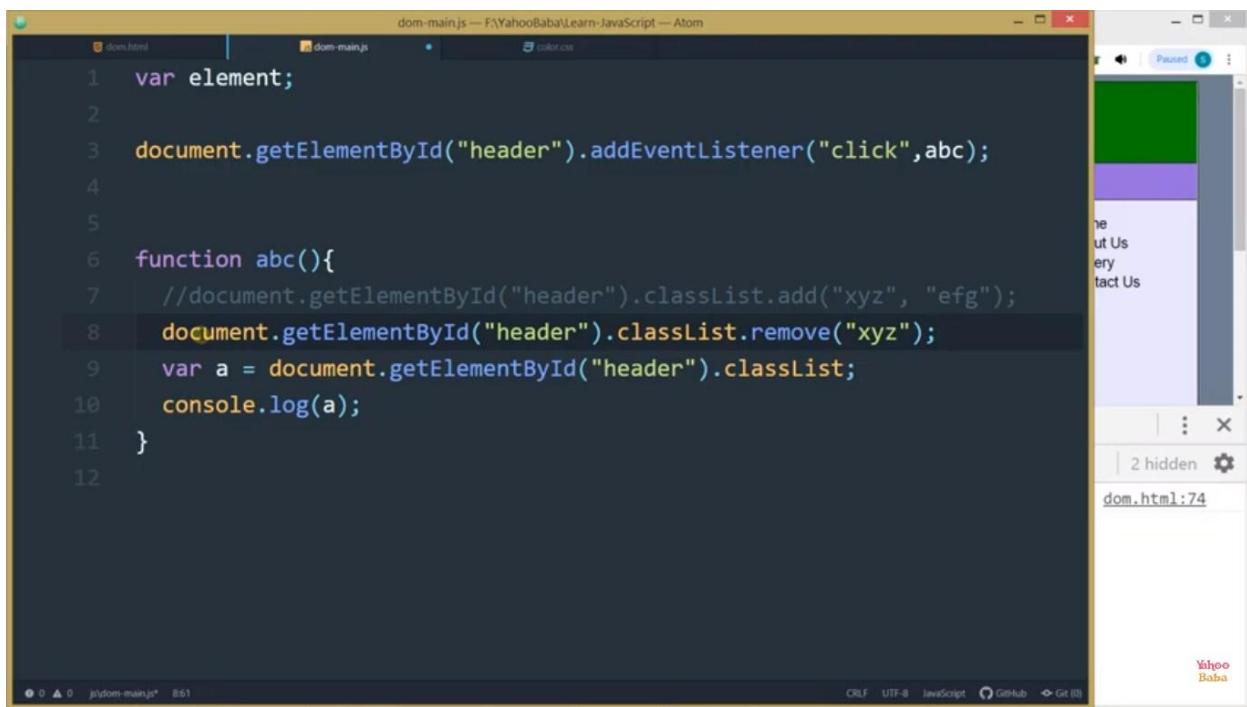

```
element.removeEventListener("ondblclick",functionName);
```

```
var element;
document.getElementById("header").addEventListener("click",abc);
function abc(){
    document.getElementById("header").classList.add("xyz", "efg");
    var a = document.getElementById("header").classList;
    console.log(a);
}
```

The screenshot shows the Atom code editor with a JavaScript file named 'dom-main.js'. The code defines a variable 'element', adds a click event listener to an element with ID 'header', and then defines a function 'abc' that adds the classes 'xyz' and 'efg' to the same element's class list. It also logs the modified class list to the console. A debugger sidebar on the right indicates the code is paused at line 12. The browser preview shows the element with the new classes applied.

```
var element;
document.getElementById("header").addEventListener("click",abc);
function abc(){
    //document.getElementById("header").classList.add("xyz", "efg");
    document.getElementById("header").classList.remove("xyz");
    var a = document.getElementById("header").classList;
    console.log(a);
}
```

This screenshot shows the same setup as the first one, but with a comment added to the line that adds classes. The code now removes the 'xyz' class from the element's class list instead. The browser preview shows the element with the 'xyz' class removed.

## JavaScript classList Methods :

- `add(class1, class2, ...)`
- `remove(class1, class2, ...)`
- `toggle(class)`
- `contains(class)`
- `item(index)`
- `Length`

A screenshot of a browser window showing developer tools. The main content area has a red background. The address bar shows "Yahoo Baba". The developer tools sidebar on the right lists "Home", "About Us", "Gallery", and "Contact Us". The code editor in the foreground contains JavaScript code:

```
1 var element;
2
3
4 document.getElementById("header").addEventListener("mouseleave",abc);
5
6 document.getElementById("header").addEventListener('click', xyz);
7
8 function abc(){
9     document.getElementById("header").style.background = "green";
10 }
11
12 function xyz(){
13     document.getElementById("header").removeEventListener('mouseleave',ab
14 }
15
16
17 //console.log(element);
```

The code includes event listeners for mouseleave and click on an element with ID "header", and functions abc() and xyz() which change the background color of the header element and remove the mouseleave listener respectively. A comment //console.log(element); is present at the bottom.

## HTML Event Attributes :

```
<button onClick="abc()></button>
```

```
<img src.." onmouseenter="xyz()>
```

The screenshot shows a web browser window with a header menu containing "Home", "About Us", "Gallery", and "Contact Us". The background of the header is green when the mouse cursor is over the image element.

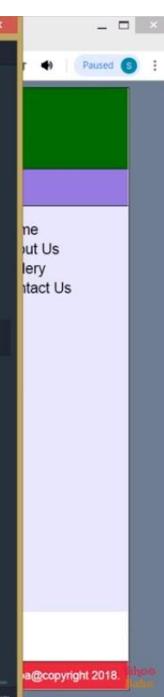

```

- innerText
- innerHTML
- getAttribute
- getAttributeNode
- Attributes

Yahoo  
Baba

The screenshot shows the Atom code editor with two files open: `dom.html` and `dom-main.js`. The `dom.html` file contains the following HTML:

```
<html>
<head>
    <title>DOM Test</title>
</head>
<body>
    <div id="content">
        Sed ut perspiciatis unde omnis iste natus error sit voluptatem accusantium doloremque laudantium, totam rem aperiam, eaque ipsa quae ab illo inventore veritatis et quasi dolorem ipsum quia dolor sit amet, consectetur adipisci velit...</div>
    <ul>
        <li>Home</li>
        <li>About Us</li>
        <li>Gallery</li>
        <li>Contact Us</li>
    </ul>
</body>
</html>
```

The `dom-main.js` file contains the following JavaScript:

```
var element;

element = document.getElementById("content").innerText;

console.log(element);
```

To the right of the code editor is a browser window showing the rendered HTML. The page has a red header and a purple footer. The main content area contains the text from the `dom.html` file. A sidebar on the right lists navigation links: Home, About Us, Gallery, and Contact Us.

A screenshot of the Atom code editor interface. On the left, there are two tabs: 'dom.html' and 'dom-main.js'. The 'dom-main.js' tab contains the following JavaScript code:

```
1 var element;
2
3 element = document.getElementById("content").innerHTML;
4
5 console.log(element);
6
```

The code editor has a status bar at the bottom showing 'js\dom-main.js 6:1'. On the right side of the screen, a browser window is open, displaying a webpage with a red header, a purple sidebar menu containing 'Home', 'About Us', 'Gallery', and 'Contact Us', and a light blue footer section.

The browser's developer tools panel is visible, showing the DOM tree. The 'header' element is selected, and its 'class' attribute is highlighted with a yellow border. The 'Elements' tab of the developer tools is active.

A screenshot of the Atom code editor interface. On the left, there are two tabs: 'dom.html' and 'dom-main.js'. The 'dom-main.js' tab contains the following JavaScript code:

```
1 ement;
2
3 t = document.getElementById("header").getAttribute("class");
4
5 e.log(element);
6
```

The code editor has a status bar at the bottom showing 'js\dom-main.js 3:64'. On the right side of the screen, a browser window is open, displaying a webpage with a red header, a purple sidebar menu containing 'Home', 'About Us', 'Gallery', and 'Contact Us', and a light blue footer section.

The browser's developer tools panel is visible, showing the DOM tree. The 'header' element is selected, and its 'class' attribute is highlighted with a yellow border. The 'Elements' tab of the developer tools is active.

A screenshot of the Atom code editor showing a file named 'dom-main.js'. The code is as follows:

```
1  element;
2
3  element = document.getElementById("header").attributes[2].name;
4
5  console.log(element);
6
```

The code highlights the line `element = document.getElementById("header").attributes[2].name;` with a yellow background. To the right of the editor is a browser window displaying a simple website with a red header, a purple sidebar menu containing 'Home', 'About Us', 'Gallery', and 'Contact Us', and a light blue footer.

## New DOM Targeting Methods :

- **querySelector** → `document.querySelector(CSS Selector)`
- **querySelectorAll** → `document.querySelectorAll(CSS Selector)`

Yahoo  
Baba

JavaScript DOM querySelector & querySelectorAll Tutorial in Hindi

```
1 var element;
2
3 document.querySelector("#header").innerHTML = "<h1>Wow</h1>";
4
5 element = document.querySelector("#header").getAttribute("class");
6
7 console.log(element);
8
```

The screenshot shows a code editor window titled "dom-main.js" in the "F:\YahooBaba\Learn-JavaScript" directory using the Atom editor. The code demonstrates how to change the innerHTML of an element and retrieve its class attribute. To the right of the editor is a browser developer tools panel showing the DOM tree. The "header" element has been modified to contain the text "Wow" and has the class "header". The developer tools also show other elements like "home", "about Us", "allery", and "ontact Us". The bottom status bar indicates the file is 5.26 KB and the total duration of the video is 9:45 minutes.

Screenshot of the Atom IDE showing a code completion dropdown for the `document.querySelectorAll` method. The code in the editor is:

```
1 var element;
2
3 document.querySelector("#header").innerHTML = "<h1>Wow</h1>";
4
5 element = document.querySelectorAll(".list");
6 console.log(element);
7
```

The cursor is on the closing parenthesis of `querySelectorAll`. A code completion dropdown titled "Code Actions" is open, showing three options:

- Select an action
- Extract to Function in global scope
- Extract to constant in enclosing scope

The right panel shows a preview of the DOM structure with a red header and a purple list item.

Screenshot of the Atom IDE showing a code completion dropdown for the `innerHTML` property of an array element. The code in the editor is:

```
1 var element;
2
3 document.querySelector("#header").innerHTML = "<h1>Wow</h1>";
4
5 element = document.querySelectorAll(".list")[1].innerHTML;
6 console.log(element);
7
```

The cursor is on the `innerHTML` property of the array element. A code completion dropdown is open, showing the following suggestion:

- innerHTML

The right panel shows a preview of the DOM structure with a red header and a purple list item.

## DOM CSS Styling Methods :

- **Style**
- **className**
- **classList**

Yahoo  
Baba

The screenshot shows the Atom code editor interface. On the left, the code file `dom-main.js` contains the following JavaScript code:

```
1 var element;
2
3 document.querySelector("#header").style.backgroundColor = "tan";
4 document.querySelector("#header").style.color = "blue";
5 element = document.querySelector("#header").style.color;
6
7 console.log(element);
8
```

On the right, the `main.css` file shows the corresponding CSS rules:

```
header main.css:42
{
  padding: 30px 0
    0 20px;
  margin: 0; Yahoo
    Baba
```

The browser preview window shows a vertical bar with different colored segments (tan, blue, purple, grey) representing the applied styles.

A screenshot of the Atom code editor. The main pane displays the following JavaScript code:

```
1 var element;
2
3 document.querySelector("#header").className = "abc";
4
5 element = document.querySelector("#header").className;
6
7 console.log(element);
8
```

The code editor interface includes tabs for 'dom.html', 'dom-main.js' (which is the active tab), 'color.css', and 'main.css'. A status bar at the bottom shows file statistics (0 0 ▲ 0 js\dom-main.js 5:54) and system information (CRLF, UTF-8, JavaScript, GitHub, Git (0)). On the right side, there's a vertical toolbar with icons for file operations and a color palette.

## JavaScript Basic Events

## Assign Events Using the HTML DOM :

```
document.getElementById(Id).onclick = functionName;
```

YahOO  
Baba

A screenshot of the Atom code editor. The left pane shows a file named 'dom-main.js' with the following code:

```
1 var element;
2
3
4 document.getElementById("header").onclick = abc;
5
6 function abc(){
7     document.getElementById("header").style.background = "green";
8 }
9
10
11 //console.log(element);
12
13
```

The right pane shows a browser preview of a web page with a green header bar and a sidebar menu:

- Home
- About Us
- Gallery
- Contact Us

At the bottom of the screen, there is a status bar with the text 'obaba@copyright 2018' and a small 'Yahoo' logo.

## DOM addEventListener() Method :

document.getElementById(Id). **addEventListener("click", functionName);**

## DOM addEventListener() Method :

```
document.getElementById(Id). addEventListener("click", functionName);
```

```
document.getElementById(Id). addEventListener("click", function(){  
    Statement  
});
```

Yahoo  
Baba

The screenshot shows the Atom code editor with two tabs: 'dom.html' and 'dom-main.js'. The 'dom-main.js' tab contains the following code:

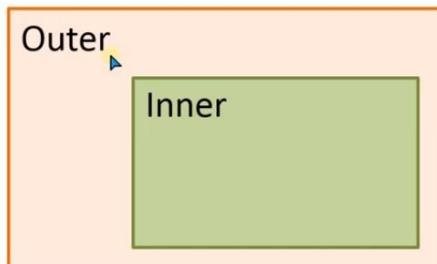

```
var element;  
  
document.getElementById("header").addEventListener("mouseenter",abc);  
document.getElementById("header").addEventListener("click",function(){  
    document.getElementById("header").style.border = "10px solid red";  
});  
  
function abc(){  
    document.getElementById("header").style.background = "green";  
}  
  
//console.log(element);
```

To the right of the editor is a browser window showing a header bar with 'Home', 'About Us', 'Gallery', and 'Contact Us' links. The background of the header bar is green, indicating it has been styled by the JavaScript code.

```
1 var element;
2
3
4 document.getElementById("header").addEventListener("click",abc);
5 document.getElementById("header").addEventListener("click",function(){
6     this.style.border = "10px solid red";
7 });
8
9 function abc(){
10     document.getElementById("header").style.background = "green";
11 }
12
13
14
15 //console.log(element);
16
```

## UseCapture:

## DOM removeEventListener() Method :

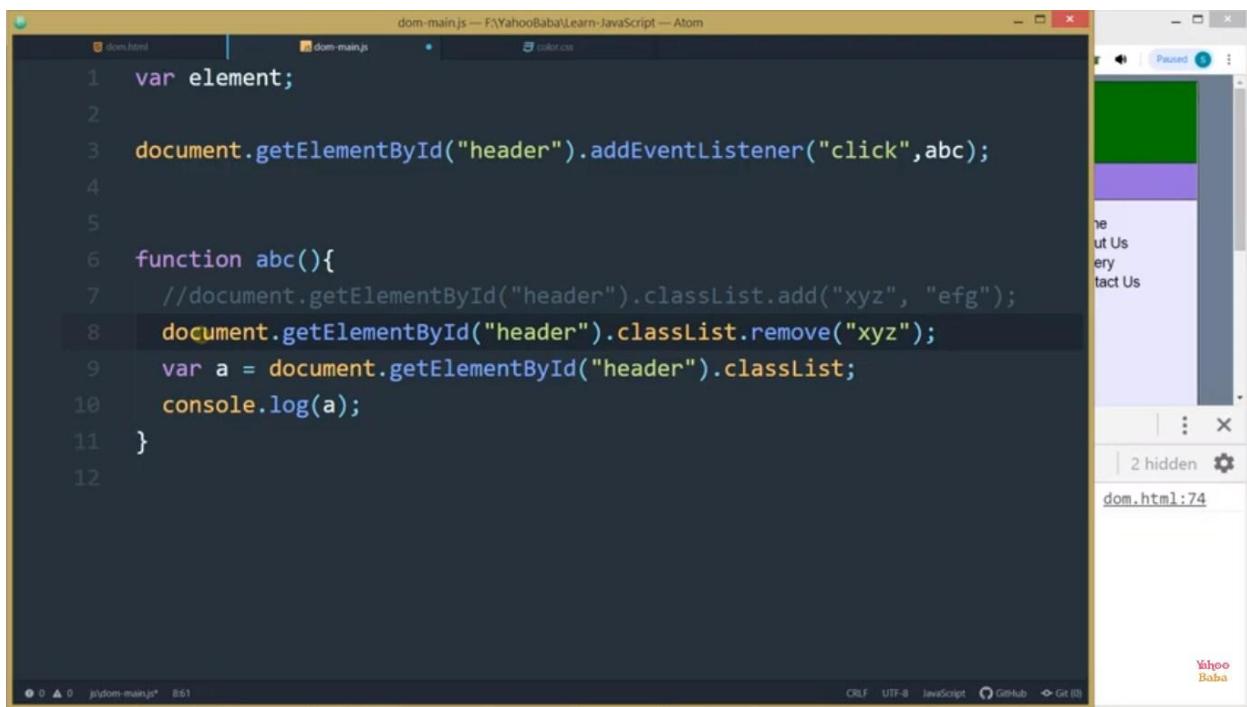

```
element.removeEventListener("ondblclick",functionName);
```

```
var element;
document.getElementById("header").addEventListener("click",abc);
function abc(){
    document.getElementById("header").classList.add("xyz", "efg");
    var a = document.getElementById("header").classList;
    console.log(a);
}
```

The screenshot shows the Atom code editor with a JavaScript file named 'dom-main.js'. The code defines a variable 'element', adds a click event listener to an element with ID 'header', and then defines a function 'abc' that adds the classes 'xyz' and 'efg' to the same element's class list. It also logs the modified class list to the console. A debugger sidebar on the right indicates the code is paused at line 12. The browser preview shows the element with the new classes applied.

```
var element;
document.getElementById("header").addEventListener("click",abc);
function abc(){
    //document.getElementById("header").classList.add("xyz", "efg");
    document.getElementById("header").classList.remove("xyz");
    var a = document.getElementById("header").classList;
    console.log(a);
}
```

This screenshot shows the same setup as the first one, but with a comment added to the line that adds classes. The code now removes the 'xyz' class from the element instead. The browser preview shows the element with the 'xyz' class removed.

## JavaScript classList Methods :

- **add(class1, class2, ...)**
- **remove(class1, class2, ...)**
- **toggle(class)**
- **contains(class)**
- **item(index)**
- **Length**

```
var element;

document.getElementById("header").addEventListener("mouseleave",abc);
document.getElementById("header").addEventListener('click', xyz);

function abc(){
    document.getElementById("header").style.background = "green";
}

function xyz(){
    document.getElementById("header").removeEventListener('mouseleave',abc);
}

//console.log(element);
```

The screenshot shows a browser window with a red header bar containing the text 'Yahoo Baba'. To the right of the header is a sidebar with links: 'Home', 'About Us', 'Gallery', and 'Contact Us'. Below the header and sidebar, there is a main content area. On the left side of the content area, there is a code editor window titled 'dom-main.js' which contains the provided JavaScript code. The code uses the `classList` methods to change the background color of an element based on mouse events.

## HTML Event Attributes :

```
<button onClick="abc()></button>
```

```
<img src.." onmouseenter="xyz()>
```

The screenshot shows a web browser window with a header menu containing "Home", "About Us", "Gallery", and "Contact Us". The background of the header is green when the mouse cursor is over the image element. The browser interface includes a title bar, tabs, and a status bar at the bottom.

```
dom-main.js — F:\YahooBaba\Learn-JavaScript — Atom
JavaScript addEventListener Method Tutorial in Hindi / Urdu

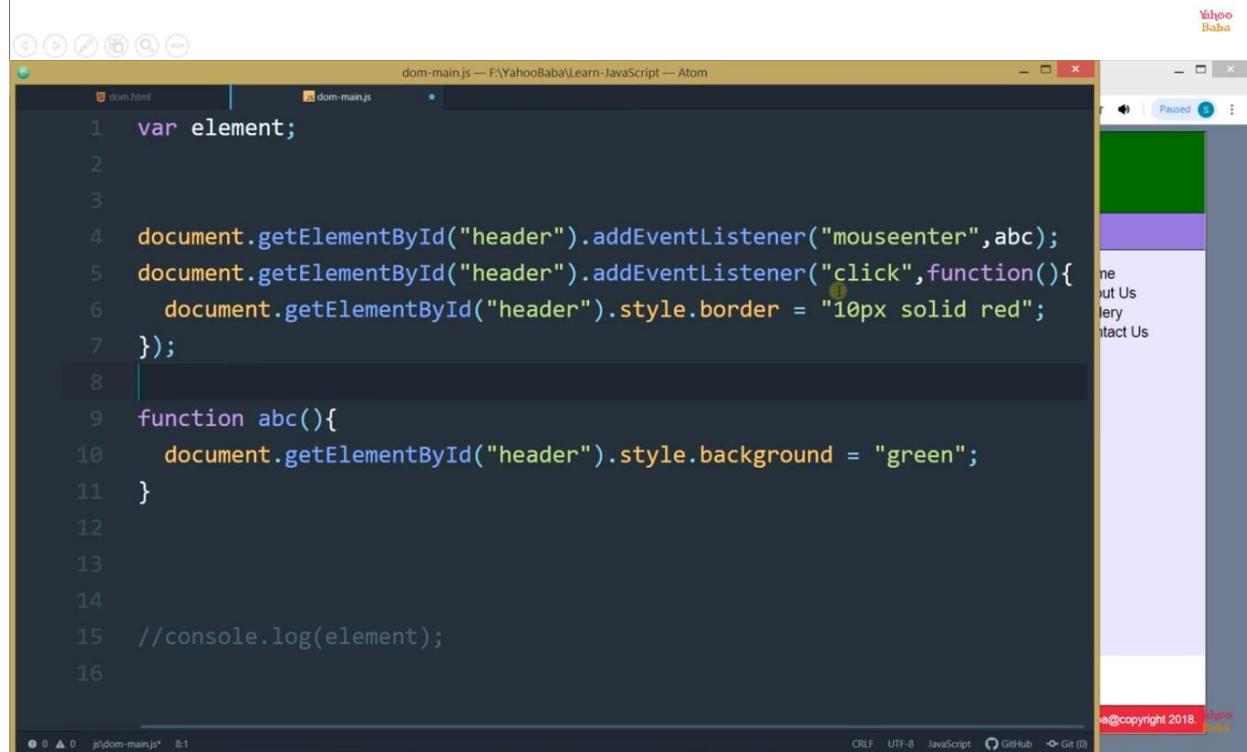

1 var element;
2
3
4 document.getElementById("header").onclick = abc;
5
6 function abc(){
7   document.getElementById("header").style.background = "green";
8 }
9
10
11 //console.log(element);
12
13
```

## DOM addEventListener() Method :

```
document.getElementById(Id). addEventListener("click", functionName);
```

```
document.getElementById(Id). addEventListener("click", function(){  
});
```

A screenshot of a web browser window titled "Yahoo Baba". The header bar is styled with a solid red border. The page content shows a navigation menu with items like Home, About Us, Gallery, and Contact Us.

```
var element;  
  
document.getElementById("header").addEventListener("mouseenter",abc);  
document.getElementById("header").addEventListener("click",function(){  
    document.getElementById("header").style.border = "10px solid red";  
});  
  
function abc(){  
    document.getElementById("header").style.background = "green";  
}  
  
//console.log(element);
```

JavaScript addEventListener Method Tutorial in Hindi / Urdu

```
1
2 document.querySelector("#inner").addEventListener('click',function(){
3     alert('Inner Div');
4 },true);
5
6 document.querySelector("#outer").addEventListener('click',function(){
7     alert('Outer Div');
8 },true);
9
```

## DOM removeEventListener() Method :

```
element.removeEventListener("ondblclick",functionName);
```

The image shows three separate windows of the Notepad+ application, each displaying a different piece of JavaScript code. The top window contains code demonstrating iteration over an array. The middle window contains code demonstrating iteration over an object. The bottom window contains code demonstrating both array and object iteration.

```
1 <script>
2 let arr="my name is Vishal";
3 /*for(var x=0;x<arr.length;x++){
4     console.log(arr[x]);
5 }*/
6 for(let key in arr){
7     console.log(arr[key]);
8 }
9 </script>
```

```
6 /*for(let key in arr){
7     console.log(arr[key]);
8 }*/
9 let obj={
10     name:"Vishal",
11     age:20
12 }
13 /*for(let x=0;x<Object.keys(obj).length;x++) {
14     console.log(obj[Object.keys(obj)[x]]);
15 }*/
16 for(let key in obj){
17     console.log(obj[key]);
18 }
19 </script>
```

```
1 <script>
2 let arr="my name is Vishal";
3 for(let key in arr){
4     console.log(arr[key]);
5 }
6 /*for(let key in arr){
7     console.log(arr[key]);
8 }*/
9 let obj={
10     name:"Vishal",
11     age:20
12 }
13 for(let x=0;x<Object.keys(obj).length;x++) {
14     console.log(obj[Object.keys(obj)[x]]);
15 }
```

### 1. Encapsulation: -

Encapsulation means wrapping up data and member function (Method) together into a single unit i.e. class.

## 2. Abstraction: -

Abstraction is the process of showing only essential/necessary features of an entity/object to the outside world and hide the other irrelevant information. For example to open your TV we only have a power button, It is not required to understand how infra-red waves are getting generated in TV remote control.

## 3. Inheritance: -

Inheritance allows a class (subclass) to acquire the properties and behavior of another class (super-class). It helps to reuse, customize and enhance the existing code. So it helps to write a code accurately and reduce the development time.

## 4. Polymorphism: -

So polymorphism means "many forms". A subclass can define its own unique behavior and still share the same functionalities or behavior of its parent/base class.

```
class square(){  
    area()  
}
```

```
Var S1 = new square();  
S1->area();
```

```
class circle(){  
    area()  
}
```

```
Var C1 = new circle();  
C1->area();
```

The image shows three vertically stacked Microsoft Edge browser windows, each displaying a different version of the same HTML file ('index.html') in Visual Studio Code. The code in all three versions is identical, demonstrating a basic JavaScript loop that logs four numbers to the console.

```
<title>Document</title>
<body>
    <h1>JavaScript Tutorial</h1>
    <script>
        let score = [80,39,70,54];
        for(let x of score){
            console.log(x);
        }
    </script>
</body>
</html>
```

The browser windows are titled 'index.html - js tutorial - Visual Studio Code'. The status bar at the bottom of each window shows the line and column numbers (e.g., 'Ln 16, Col 28'), the number of spaces (e.g., 'Spaces: 4'), and the encoding (e.g., 'UTF-8'). The bottom-most window also shows the file path 'index.html - js tutorial - Visual Studio Code'.

Below the browser windows, there is a screenshot of a Microsoft Word document. The title of the document is 'JavaScript Type Casting'. The text within the document states: 'Converting one type of data value to another type is called as type casting. There are **two** types of type casting: Implicit type casting (Coercion): Done by JavaScript Engine Explicit type casting (Conversion): Done by programmers'. The word 'Implicit type casting:' is bolded. The document includes a toolbar with various formatting options like Cut, Copy, Paste, Font, Paragraph, and Styles.

**Implicit type casting:**  
If required JavaScript engine automatically converts one type of value to another type.  
This is known as implicit type casting.

**Ex:**

```
document.write(2+4.3); // 6.3
document.write("2" + 2 ); // "22"
document.write(2 + "2"); // "22"
```

The image shows a dual-monitor setup. The left monitor displays Sublime Text with an open file named 'foreach.html' containing JavaScript code. The right monitor displays Visual Studio Code with an open file named 'index.html' containing HTML and JavaScript code. A yellow banner at the bottom of the page provides information about the `forEach()` method.

The `forEach()` method calls a function once for each element in an array, in order.

# forEach() Method

Syntax: `arr.forEach(callback(currentValue [, index [, array]])[, thisArg])`

Argument	Description
<code>currentValue</code>	Required. The value of the current element
<code>index</code>	Optional. The array index of the current element
<code>arr</code>	Optional. The array object the current element belongs to

The image shows three vertically stacked instances of the Sublime Text editor, all displaying the same file content: `foreachs.html`. The code is a simple JavaScript snippet demonstrating a `foreach` loop.

```
4
5 // console.log(myFavProg[0]);
6 // console.log(myFavProg[1]);
7 // console.log(myFavProg[2]);
8
9 // for (let x=0; x<myFavProg.length; x++){
10 //   console.log(myFavProg[x]);
11 // }
12
13 myFavProg.forEach(function(currValue){
14   console.log(currValue);
15 })
16
17 </script>
```

The code is in `INSERT MODE` at Line 13, Column 38 in the first window, Line 13, Column 38 in the second window, and Line 13, Column 37 in the third window. The status bar in each window indicates `Tab Size: 4` and `HTML`.

In the bottom-most window, the status bar also shows `4 characters selected`.

In programming languages we often say “An object is an instance of a class”.

This means that, using a class, I can create many objects and they all share methods and properties.

Since objects can be enhanced, there are many ways to create objects sharing methods and properties. But we want the simplest one.

## Bind `this`

For methods in React, the `this` keyword should represent the component that owns the method.

That is why you should use arrow functions. With arrow functions, `this` will always represent the object that defined the arrow function.

# Why Arrow Functions?

In class components, the `this` keyword is not defined by default, so with regular functions the `this` keyword represents the object that called the method, which can be the global window object, a HTML button, or whatever.

Read more about binding `this` in our [React ES6 'What About this?'](#) chapter.

If you *must* use regular functions instead of arrow functions you have to bind `this` to the component instance using the `bind()` method:

## bind() Method

by this method, we can bind an object to a common function, so that the function gives different result when its need.

Welcome to master CSS Class

```
margin: 0; padding: 0;
box-sizing: border-box;
}
.parent_div{
width: 100vw;
height: 100vh;
background: #2980b9;
display: flex;
justify-content: center;
align-items: center;
}

.child_div{
width: 60vw;
height: 60vh;
background:#1abc9c;
/*position: absolute;
left: 50%;
```

```

}
.parent_div{
width: 100vw;
height: 100vh;
background: #2980b9;
/*display: flex;
justify-content: center;
align-items: center;*/
display: grid;
place-items:center;
}

.child_div{
width: 60vw;
height: 60vh;
background:#1abc9c;
/*position: absolute;
left: 50%;
```

```

<script>
    function Employee(firstName,lastName)
    {
        this.firstName=firstName;
        this.lastName=lastName;
    }

    Employee.prototype.company="Javatpoint"

    var employee1=new Employee("Martin","Roy");
    var employee2=new Employee("Duke", "William");
    document.writeln(employee1.firstName+" "+employee1.lastName+" "+employee1.company+"<b>r"+");
    document.writeln(employee2.firstName+" "+employee2.lastName+" "+employee2.company);
</script>

```

Let's see an example to add a new property to the constructor function.

```

<script>
    function Employee(firstName,lastName)
    {
        this.firstName=firstName;
        this.lastName=lastName;
    }

    Employee.prototype.company="Javatpoint"

    var employee1=new Employee("Martin","Roy");
    var employee2=new Employee("Duke", "William");
    document.writeln(employee1.firstName+" "+employee1.lastName+" "+employee1.company+"<b>r"+");
    document.writeln(employee2.firstName+" "+employee2.lastName+" "+employee2.company);
</script>

```

The screenshot shows a Visual Studio Code interface with two tabs: 'index.html' and 'index.js'. The 'index.js' tab contains the following code:

```

function Student(firstName, lastName, subject) {
    this.firstName = firstName;
    this.lastName = lastName;
    this.subject = subject;
    this.greet = function(){
        console.log(`${this.firstName} ${this.lastName}`);
    }
}

let student1 = new Student("John", "Doe", "CS");
student1.greet();

function Employee(firstName, lastName, department) {
    this.firstName = firstName;
    this.lastName = lastName;
    this.department = department;
    this.greet = function(){
        console.log(`${this.firstName} ${this.lastName}`);
    }
}

let emp1 = new Employee("Jason", "Smith");
emp1.greet();

```

To the right, a browser window displays the output of the script. The console log entries are:

Output	Line Number
John Doe	index.js:6
Jason Smith	index.js:18

At the bottom right of the browser window, it says 'CHEEZYCODE'.

```
const person = {  
    firstName:"John",  
    lastName: "Doe",  
    fullName: function () {  
        return this.firstName + " " + this.lastName;  
    }  
}  
  
console.log( person.fullName() ); // John Doe
```

JS

```
const person = {  
    fullName: function() {  
        return this.firstName + " " + this.lastName;  
    }  
}  
  
const person1 = {  
    firstName:"John",  
    lastName: "Doe"  
}  
const person2 = {  
    firstName:"Mary",  
    lastName: "Doe"  
}  
  
console.log( person.fullName.call(person1) ); // John Doe  
console.log( person.fullName.call(person2) ); // Mary Doe
```

JS

```
const obj = { name: "John" };  
  
let greeting = function(a,b){  
    return `${a} ${this.name}. ${b}`;  
};  
  
greeting();  
  
console.log( greeting.call(obj, "Hello", "How are you?") );  
// returns: Hello John. How are you?
```

JS

```
const obj = { name: "John" };

let greeting = function(a,b){
    return `${a} ${this.name}. ${b}`;
};

console.log( greeting.apply(obj, ["Hello", "How are you?"]) );
// returns: Hello John. How are you?
```

JS

```
const obj = { name: "John" };

let greeting = function(a,b){
    return `${a} ${this.name}. ${b}`;
};

let bound = greeting.bind(obj);

console.log( bound("Hello", "How are you?") );
// returns: Hello John. How are you?
```

JS

## Array – findIndex() Function :

```
var ages = [10 , 23 , 19 , 20];
```

```
var adultAge = 18;
```

```
ages >= adultAge
```

### findIndex(Function Name)

findIndex() method returns the index of the first element in an array that pass a test

## Array – find() Function :

```
var ages = [10 , 23 , 19 , 20];  
var adultAge = 18;  
ages >= adultAge
```

### find(Function Name)

find() method returns the value of the first element in an array that pass a test

The screenshot displays a development environment with two windows. On the left, an Atom code editor shows the file 'map.html' with the following code:

```
<!DOCTYPE html>  
<html>  
<head>  
  <title>JavaScript</title>  
  <script>  
    var ary = [11,4,9,16];  
  
    var b = ary.map(test);  
    document.write(b);  
  
    function test(x){  
      return x * 10;  
    }  
  </script>  
</head>  
<body>
```

On the right, a browser window titled 'JavaScript' shows the output of the code: "110,40,90,160". A watermark for "Yahoo Baba" is visible in the bottom right corner of the browser window.

# JavaScript Interview Questions

JavaScript interview questions and answers for provides a list of top 20 interview questions. The frequently asked JavaScript interview questions with answers for beginners and professionals are given below.

## 1) What is JavaScript?

**JavaScript** is a *scripting language*. It is different from Java language. It is object-based, lightweight, cross-platform translated language. It is widely used for client-side validation. The JavaScript Translator (embedded in the browser) is responsible for translating the JavaScript code for the web browser. [More details.](#)

---

## 2) List some features of JavaScript.

Some of the features of JavaScript are:

- Lightweight
- Interpreted programming language
- Good for the applications which are network-centric
- Complementary to Java
- Complementary to HTML
- Open source

Cross-platform

---

## 3) Who developed JavaScript, and what was the first name of JavaScript?

JavaScript was developed by Brendan Eich, who was a Netscape programmer. Brendan Eich developed this new scripting language in just ten days in the year September 1995. At the time of its launch, JavaScript was initially called Mocha. After that, it was called Live Script and later known as JavaScript.

---

#### 4) List some of the advantages of JavaScript.

Some of the advantages of JavaScript are:

- Server interaction is less
  - Feedback to the visitors is immediate
  - Interactivity is high
  - Interfaces are richer
- 

#### 5) List some of the disadvantages of JavaScript.

Some of the disadvantages of JavaScript are:

- No support for multithreading
  - No support for multiprocessing
  - Reading and writing of files is not allowed
  - No support for networking applications.
- 

#### 6) Define a named function in JavaScript.

The function which has named at the time of definition is called a named function. For example

1. `function msg()`
  2. `{`
  3. `document.writeln("Named Function");`
  4. `}`
  5. `msg();`
- 

#### 7) Name the types of functions

The types of function are:

- Named - These type of functions contains name at the time of definition. For Example:

1. function display()
2. {
3. document.writeln("Named Function");
4. }
5. display();

- Anonymous - These type of functions doesn't contain any name. They are declared dynamically at runtime.

1. var display=function()
2. {
3. document.writeln("Anonymous Function");
4. }
5. display();

---

## 8) Define anonymous function

It is a function that has no name. These functions are declared dynamically at runtime using the function operator instead of the function declaration. The function operator is more flexible than a function declaration. It can be easily used in the place of an expression. For example:

1. var display=function()
2. {
3. alert("Anonymous Function is invoked");
4. }
5. display();

---

## 9) Can an anonymous function be assigned to a variable?

Yes, you can assign an anonymous function to a variable.

---

## 10) In JavaScript what is an argument object?

The variables of JavaScript represent the arguments that are passed to a function.

---

## 11) Define closure.

In JavaScript, we need closures when a variable which is defined outside the scope in reference is accessed from some inner scope.

1. var num = 10;
  2. function sum()
  3. {
  4. document.writeln(num+num);
  5. }
  6. sum();
- 

## 12) If we want to return the character from a specific index which method is used?

The JavaScript string charAt() method is used to find out a char value present at the specified index. The index number starts from 0 and goes to n-1, where n is the length of the string. The index value can't be a negative, greater than or equal to the length of the string. For example:

1. var str="Javatpoint";
  2. document.writeln(str.charAt(4));
- 

## 13) What is the difference between JavaScript and JScript?

Netscape provided the JavaScript language. Microsoft changed the name and called it JScript to avoid the trademark issue. In other words, you can say JScript is the same as JavaScript, but Microsoft provides it.

---

## 14) How to write a hello world example of JavaScript?

A simple example of JavaScript hello world is given below. You need to place it inside the body tag of HTML.

1. `<script type="text/javascript">`
2. `document.write("JavaScript Hello World!");`
3. `</script>`

[More details.](#)

---

## 15) What are the key differences between Java and JavaScript? / How is JavaScript different from Java?

JavaScript is a lightweight programming language (most commonly known as scripting language) developed by Netscape, Inc. It is used to make web pages interactive. It is not a part of the Java platform. Following is a list of some key differences between Java and JavaScript

### A list of key differences between Java and JavaScript

Java	JavaScript
Java is a complete and strongly typed programming language used for backend coding. In Java, variables must be declared first to use in the program, and the type of a variable is checked at compile-time.	JavaScript is a weakly typed, lightweight programming language (most commonly known as scripting language) and has more relaxed syntax and rules.
Java is an object-oriented programming (OOPS) language or structured programming languages such as C, C++, or .Net.	JavaScript is a client-side scripting language, and it doesn't fully support the OOPS concept. It resides inside the HTML documents and is used to make web pages interactive (not achievable with simple HTML).
Java creates applications that can run in any virtual machine (JVM) or browser.	JavaScript code can run only in the browser, but it can now run on the server via Node.js.

The Java code needs to be compiled.	The JavaScript code doesn't require to be complied.
Java Objects are class-based. You can't make any program in Java without creating a class.	JavaScript Objects are prototype-based.
Java is a Complete and Standalone language that can be used in backend coding.	JavaScript is assigned within a web page and integrates with its HTML content.
Java programs consume more memory.	JavaScript code is used in HTML web pages and requires less memory.
The file extension of the Java program is written as ".Java" and it translates source code into bytecodes which are then executed by JVM (Java Virtual Machine).	The JavaScript file extension is written as ".js" and it is interpreted but not compiled. Every browser has a JavaScript interpreter to execute the JS code.
Java supports multithreading.	JavaScript doesn't support multithreading.
Java uses a thread-based approach to concurrency.	JavaScript uses an event-based approach to concurrency.

## 16) How to use external JavaScript file?

I am assuming that js file name is message.js, place the following script tag inside the head tag.

1. `<script type="text/javascript" src="message.js"></script>`

[More details.](#)

---

## 17) Is JavaScript case sensitive language?

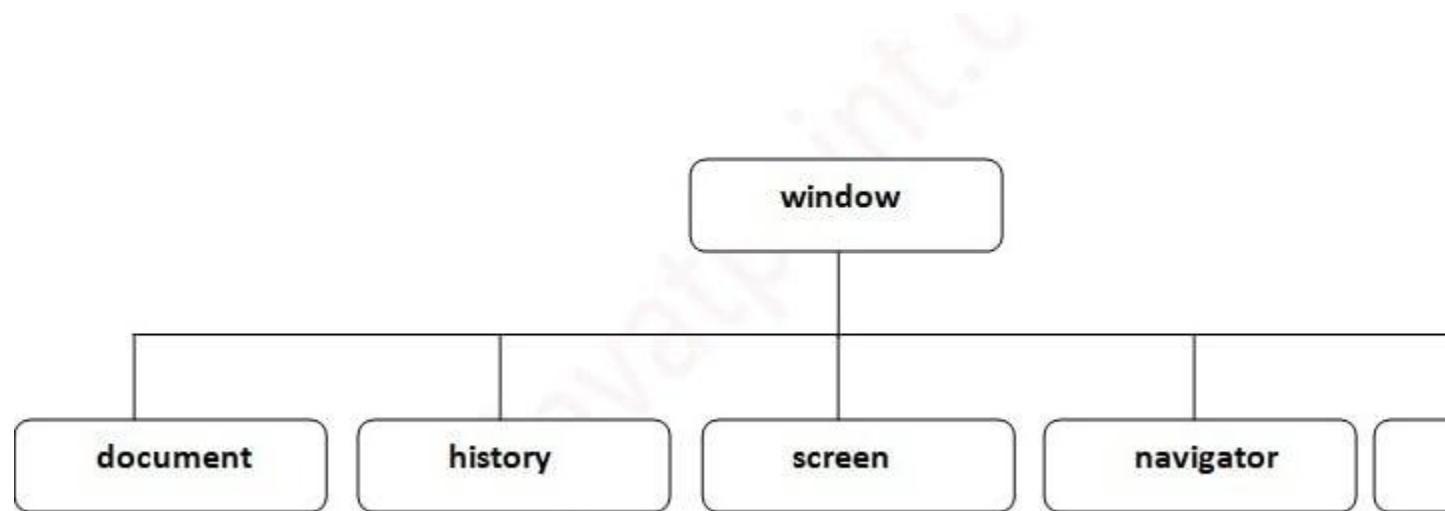

Yes, JavaScript is a case sensitive language. For example:

1. Var msg = "JavaScript is a case-sensitive language"; //Here, var should be used to declare a variable
2. function display()
3. {

4. document.writeln(msg); // It will not display the result.
  5. }
  6. display();
- 

## 18) What is BOM?

**BOM** stands for *Browser Object Model*. It provides interaction with the browser. The default object of a browser is a window. So, you can call all the functions of the window by specifying the window or directly. The window object provides various properties like document, history, screen, navigator, location, innerHeight, innerWidth,

[More Details: Browser Object Model](#)

---

## 19) What is DOM? What is the use of document object?

**DOM** stands for *Document Object Model*. A document object represents the HTML document. It can be used to access and change the content of HTML.

[More Details: Document Object Model](#)

---

## 20) What is the use of window object?

The window object is created automatically by the browser that represents a window of a browser. It is not an object of JavaScript. It is a browser object.

The window object is used to display the popup dialog box. Let's see with description.

Method	Description
alert()	displays the alert box containing the message with ok button.
confirm()	displays the confirm dialog box containing the message with ok and cancel button.
prompt()	displays a dialog box to get input from the user.
open()	opens the new window.
close()	closes the current window.
setTimeout()	performs the action after specified time like calling function, evaluating expressions.

[More details.](#)

---

## 21) What is the use of history object?

The history object of a browser can be used to switch to history pages such as back and forward from the current page or another page. There are three methods of history object.

1. history.back() - It loads the previous page.
2. history.forward() - It loads the next page.
3. history.go(number) - The number may be positive for forward, negative for backward. It loads the given page number.

[More details.](#)

---

## 22) How to write a comment in JavaScript?

There are two types of comments in JavaScript.

1. Single Line Comment: It is represented by // (double forward slash)
2. Multi-Line Comment: Slash represents it with asterisk symbol as /\* write comment here \*/

[More details.](#)

---

## 23) How to create a function in JavaScript?

To create a function in JavaScript, follow the following syntax.

1. `function function_name(){`
2. `//function body`
3. `}`

[More details.](#)

---

## 24) What are the different data types present in JavaScript?

There are two types of data types in JavaScript:

- o Primitive data types
- o Non- Primitive data types

### **Primitive data types**

The primitive data types are as follows:

**String:** The string data type represents a sequence of characters. It is written within quotes and can be represented using a single or a double quote.

#### **Example:**

1. `var str1 = "Hello JavaTpoint"; //using double quotes`
2. `var str2 = 'Hello Javatpoint'; //using single quotes`

**Number:** The number data type is used to represent numeric values and can be written with or without decimals.

#### **Example:**

1. `var x = 5; //without decimal`
2. `var y = 5.0; //with decimal`

**Boolean:** The Boolean data type is used to represent a Boolean value, either false or true. This data type is generally used for conditional testing.

**Example:**

1. var x = 5;
2. var y = 6;
3. var z = 5;
4. (x == y) // returns false
5. (x == z) //returns true

**BigInt:** The BigInt data type is used to store numbers beyond the Number data type limitation. This data type can store large integers and is represented by adding "n" to an integer literal.

**Example:**

1. var bigInteger = 123456789012345678901234567890;
2. // This is an example of bigInteger.

**Undefined:** The Undefined data type is used when a variable is declared but not assigned. The value of this data type is undefined, and its type is also undefined.

**Example:**

1. var x; // value of x is undefined
2. var y = undefined; // You can also set the value of a variable as undefined.

**Null:** The Null data type is used to represent a non-existent, null, or a invalid value i.e. no value at all.

**Example:**

1. var x = null;

**Symbol:** Symbol is a new data type introduced in the ES6 version of JavaScript. It is used to store an anonymous and unique value.

**Example:**

```
1. var symbol1 = Symbol('symbol');
```

**typeof:** The typeof operator is used to determine what type of data a variable or operand contains. It can be used with or without parentheses (typeof(x) or typeof x). This is mainly used in situations when you need to process the values of different types.

**Example:**

1. typeof 10; // Returns: "number"
2. typeof 10.0; // Returns: "number"
3. typeof 2.5e-4; // Returns: "number"
4. typeof Infinity; // Returns: "number"
5. typeof NaN; // Returns: "number". Despite being "Not-A-Number"
6. // Strings
7. typeof ""; // Returns: "string"
8. typeof 'Welcome to JavaTpoint'; // Returns: "string"
9. typeof '12'; // Returns: "string". Number within quotes is typeof string
10. // Booleans
11. typeof true; // Returns: "boolean"
12. typeof false; // Returns: "boolean"
13. // Undefined
14. typeof undefined; // Returns: "undefined"
15. typeof undeclaredVariable; // Returns: "undefined"
16. // Null
17. typeof Null; // Returns: "object"
18. // Objects
19. typeof {name: "John", age: 18}; // Returns: "object"
20. // Arrays
21. typeof [1, 2, 3]; // Returns: "object"
22. // Functions
23. typeof function(){}; // Returns: "function"

### Non-Primitive data types

In the above examples, we can see that the primitive data types can store only a single value. To store multiple and complex values, we have to use non-primitive data types.

The non-primitive data types are as follows:

**Object:** The Object is a non-primitive data type. It is used to store collections of data. An object contains properties, defined as a key-value pair. A property key (name) is always a string, but the value can be any data type, such as strings, numbers, Booleans, or complex data types like arrays, functions, and other objects.

**Example:**

```
1. // Collection of data in key-value pairs
2. var obj1 = {
3.   x: 123,
4.   y: "Welcome to JavaTpoint",
5.   z: function(){
6.     return this.x;
7.   }
8. }
```

**Array:** The Array data type is used to represent a group of similar values. Every value in an array has a numeric position, called its index, and it may contain data of any data type-numbers, strings, Booleans, functions, objects, and even other arrays. The array index starts from 0 so that the first array element is arr[0], not arr[1].

**Example:**

```
1. var colors = ["Red", "Yellow", "Green", "Orange"];
2. var cities = ["Noida", "Delhi", "Ghaziabad"];
3. alert(colors[2]); // Output: Green
4. alert(cities[1]); // Output: Delhi
```

[More details.](#)

---

## 25) What is the difference between == and ===?

The == operator checks equality only whereas === checks equality, and data type, i.e., a value must be of the same type.

---

## 26) How to write HTML code dynamically using JavaScript?

The innerHTML property is used to write the HTML code using JavaScript dynamically. Let's see a simple example:

1. `document.getElementById('mylocation').innerHTML = "<h2>This is heading using JavaScript</h2>";`

[More details.](#)

---

## 27) How to write normal text code using JavaScript dynamically?

The innerText property is used to write the simple text using JavaScript dynamically. Let's see a simple example:

1. `document.getElementById('mylocation').innerText = "This is text using JavaScript";`

[More details.](#)

---

## 28) How to create objects in JavaScript?

There are 3 ways to create an object in JavaScript.

1. By object literal
2. By creating an instance of Object
3. By Object Constructor

Let's see a simple code to create an object using object literal.

1. `emp = {id:102, name:"Rahul Kumar", salary:50000}`

[More details.](#)

---

## 29) How to create an array in JavaScript?

There are 3 ways to create an array in JavaScript.

1. By array literal

2. By creating an instance of Array
3. By using an Array constructor

Let's see a simple code to create an array using object literal.

1. var emp=["Shyam","Vimal","Ratan"];

[More details.](#)

---

### 30) What does the isNaN() function?

The isNaN() function returns true if the variable value is not a number. For example:

```
1. function number(num) {  
2.   if (isNaN(num)) {  
3.     return "Not a Number";  
4.   }  
5.   return "Number";  
6. }  
7. console.log(number('1000F'));  
8. // expected output: "Not a Number"  
9.  
10. console.log(number('1000'));  
11. // expected output: "Number"
```

---

### 31) What is the output of 10+20+"30" in JavaScript?

3030 because 10+20 will be 30. If there is numeric value before and after +, it treats as binary + (arithmetic operator).

```
1. function display()  
2. {  
3.   document.writeln(10+20+"30");  
4. }  
5. display();
```

---

## 32) What is the output of "10"+20+30 in JavaScript?

102030 because after a string all the + will be treated as string concatenation operator (not binary +).

```
1. function display()
2. {
3.   document.writeln("10"+20+30);
4. }
5. display();
```

---

## 33) Difference between Client side JavaScript and Server side JavaScript?

**Client-side JavaScript** comprises the basic language and predefined objects which are relevant to running JavaScript in a browser. The client-side JavaScript is embedded directly by in the HTML pages. The browser interprets this script at runtime.

**Server-side JavaScript** also resembles client-side JavaScript. It has a relevant JavaScript which is to run in a server. The server-side JavaScript are deployed only after compilation.

---

## 34) In which location cookies are stored on the hard disk?

The storage of cookies on the hard disk depends on the OS and the browser.

The Netscape Navigator on Windows uses a cookies.txt file that contains all the cookies. The path is c:\Program Files\Netscape\Users\username\cookies.txt

The Internet Explorer stores the cookies on a file username@website.txt. The path is: c:\Windows\Cookies\username@Website.txt.

---

## 35) What's the difference between event.preventDefault() and event.stopPropagation() methods in JavaScript?

In JavaScript, the `event.preventDefault()` method is used to prevent the default behavior of an element.

**For example:** If you use it in a form element, it prevents it from submitting. If used in an anchor element, it prevents it from navigating. If used in a contextmenu, it prevents it from showing or displaying.

On the other hand, the `event.stopPropagation()` method is used to stop the propagation of an event or stop the event from occurring in the bubbling or capturing phase.

---

### 36) What is the real name of JavaScript?

The original name was **Mocha**, a name chosen by Marc Andreessen, founder of Netscape. In September of 1995, the name was changed to LiveScript. In December 1995, after receiving a trademark license from Sun, the name JavaScript was adopted.

---

### 37) How can you check if the `event.preventDefault()` method was used in an element?

When we use the `event.defaultPrevent()` method in the event object returns a Boolean indicating that the `event.preventDefault()` was called in a particular element.

---

### 38) What is the difference between undefined value and null value?

**Undefined value:** A value that is not defined and has no keyword is known as undefined value. For example:

1. `int number;//Here, a number has an undefined value.`

**Null value:** A value that is explicitly specified by the keyword "null" is known as a null value. For example:

1. `String str=null;//Here, str has a null value.`
-

## 39) How to set the cursor to wait in JavaScript?

The cursor can be set to wait in JavaScript by using the property "cursor". The following example illustrates the usage:

1. `<script>`
  2. `window.document.body.style.cursor = "wait";`
  3. `</script>`
- 

## 40) What is this [[[ ]]]?

This is a three-dimensional array.

1. `var myArray = [[[ ]]];`
- 

## 41) Are Java and JavaScript same?

No, Java and JavaScript are the two different languages. Java is a robust, secured and object-oriented programming language whereas JavaScript is a client-side scripting language with some limitations.

---

## 42) What is negative infinity?

Negative Infinity is a number in JavaScript which can be derived by dividing the negative number by zero. For example:

1. `var num=-5;`
  2. `function display()`
  3. `{`
  4. `document.writeln(num/0);`
  5. `}`
  6. `display();`
  7. `//expected output: -Infinity`
-

## 43) What is the difference between View state and Session state?

"View state" is specific to a page in a session whereas "Session state" is specific to a user or browser that can be accessed across all pages in the web application.

---

## 44) What are the pop-up boxes available in JavaScript?

- Alert Box
- Confirm Box
- Prompt Box

Example of alert() in JavaScript

```
1. <script type="text/javascript">
2. function msg(){
3.   alert("Hello Alert Box");
4. }
5. </script>
6. <input type="button" value="click" onclick="msg()" />
```

Example of confirm() in JavaScript

```
1. <script type="text/javascript">
2. function msg(){
3.   var v= confirm("Are u sure?");
4.   if(v==true){
5.     alert("ok");
6.   }
7.   else{
8.     alert("cancel");
9.   }
10.
11. }
12. </script>
13.
```

14. <input type="button" value="delete record" onclick="msg()"/>

Example of prompt() in JavaScript

```
1. <script type="text/javascript">
2. function msg(){
3. var v= prompt("Who are you?");
4. alert("I am "+v);
5.
6. }
7. </script>
8.
9. <input type="button" value="click" onclick="msg()"/>
```

---

45) How can we detect OS of the client machine using JavaScript?

The **navigator.appVersion** string can be used to detect the operating system on the client machine.

---

46) How to submit a form using JavaScript by clicking a link?

Let's see the JavaScript code to submit the form by clicking the link.

```
1. <form name="myform" action="index.php">
2. Search: <input type='text' name='query' />
3. <a href="javascript: submitform()">Search</a>
4. </form>
5. <script type="text/javascript">
6. function submitform()
7. {
8. document.myform.submit();
9. }
10. </script>
```

---

## 47) Is JavaScript faster than ASP script?

Yes, because it doesn't require web server's support for execution.

---

## 48) How to change the background color of HTML document using JavaScript?

1. `<script type="text/javascript">`
  2. `document.body.bgColor="pink";`
  3. `</script>`
- 

## 49) How to handle exceptions in JavaScript?

By the help of try/catch block, we can handle exceptions in JavaScript. JavaScript supports try, catch, finally and throw keywords for exception handling.

---

## 50) How to validate a form in JavaScript?

1. `<script>`
2. `function validateform(){`
3. `var name=document.myform.name.value;`
4. `var password=document.myform.password.value;`
5.
6. `if (name==null || name==""){`
7. `alert("Name can't be blank");`
8. `return false;`
9. `}else if(password.length<6){`
10. `alert("Password must be at least 6 characters long.");`
11. `return false;`
12. `}`
13. `}`

```
14. </script>
15. <body>
16. <form name="myform" method="post" action="abc.jsp" onsubmit="return validateform()" >
17. Name: <input type="text" name="name"><br/>
18. Password: <input type="password" name="password"><br/>
19. <input type="submit" value="register">
20. </form>
```

Visit here: [JavaScript form validation](#).

---

## 51) How to validate email in JavaScript?

```
1. <script>
2. function validateemail()
3. {
4. var x=document.myform.email.value;
5. var atposition=x.indexOf("@");
6. var dotposition=x.lastIndexOf(".");
7. if (atposition<1 || dotposition<atposition+2 || dotposition+2>=x.length){
8. alert("Please enter a valid e-
mail address \n atposition:"+atposition+"\n dotposition:"+dotposition);
9. return false;
10. }
11. }
12. </script>
13. <body>
14. <form name="myform" method="post" action="#" onsubmit="return validateemail();"
>
15. Email: <input type="text" name="email"><br/>
16.
17. <input type="submit" value="register">
18. </form>
```

Visit here: [JavaScript Email validation](#).

---

## 52) What is this keyword in JavaScript?

The this keyword is a reference variable that refers to the current object. For example:

```
1. var address=
2. {
3.   company:"Javatpoint",
4.   city:"Noida",
5.   state:"UP",
6.   fullAddress:function()
7.   {
8.     return this.company+" "+this.city+" "+this.state;
9.   }
10. };
11. var fetch=address.fullAddress();
12. document.writeln(fetch);
```

---

## 53) What is the requirement of debugging in JavaScript?

JavaScript didn't show any error message in a browser. However, these mistakes can affect the output. The best practice to find out the error is to debug the code. The code can be debugged easily by using web browsers like Google Chrome, Mozilla Firebox.

To perform debugging, we can use any of the following approaches:

- Using console.log() method
  - Using debugger keyword
- 

## 54) What is the use of debugger keyword in JavaScript?

JavaScript debugger keyword sets the breakpoint through the code itself. The debugger stops the execution of the program at the position it is applied. Now, we can start the flow of execution manually. If an exception occurs, the execution will stop again on that particular line.. For example:

```
1. function display()
2. {
3.   x = 10;
4.   y = 15;
5.   z = x + y;
6.   debugger;
7.   document.write(z);
8.   document.write(a);
9. }
10. display();
```

---

## 55) What is the role of a strict mode in JavaScript?

The JavaScript strict mode is used to generates silent errors. It provides "use strict"; expression to enable the strict mode. This expression can only be placed as the first statement in a script or a function. For example:

```
1. "use strict";
2. x=10;
3. console.log(x);
```

---

## 57) What is the use of Math object in JavaScript?

The JavaScript math object provides several constants and methods to perform a mathematical operation. Unlike date object, it doesn't have constructors. For example:

```
1. function display()
2. {
3.   document.writeln(Math.random());
4. }
```

---

5. display();

## 58) What is the use of a Date object in JavaScript?

The JavaScript date object can be used to get a year, month and day. You can display a timer on the webpage by the help of JavaScript date object.

```
1. function display()
2. {
3.   var date=new Date();
4.   var day=date.getDate();
5.   var month=date.getMonth()+1;
6.   var year=date.getFullYear();
7.   document.write("<br>Date is: "+day+"/"+month+"/"+year);
8. }
9. display();
```

---

## 59) What is the use of a Number object in JavaScript?

The JavaScript number object enables you to represent a numeric value. It may be integer or floating-point. JavaScript number object follows the IEEE standard to represent the floating-point numbers.

```
1. function display()
2. {
3.   var x=102;//integer value
4.   var y=102.7;//floating point value
5.   var z=13e4;//exponent value, output: 130000
6.   var n=new Number(16);//integer value by number object
7.   document.write(x+" "+y+" "+z+" "+n);
8. }
9. display();
```

---

## 60) What is the use of a Boolean object in JavaScript?

The JavaScript Boolean is an object that represents value in two states: true or false. You can create the JavaScript Boolean object by Boolean() constructor.

```
1. function display()
2. {
3.     document.writeln(10<20);//true
4.     document.writeln(10<5);//false
5. }
6. display();
```

---

## 61) What is the use of a TypedArray object in JavaScript?

The JavaScript TypedArray object illustrates an array like a view of an underlying binary data buffer. There is any number of different global properties, whose values are TypedArray constructors for specific element types.

```
1. function display()
2. {
3.     var arr1= [1,2,3,4,5,6,7,8,9,10];
4.     arr1.copyWithin(2) ;
5.     document.write(arr1);
6. }
7. display();
```

---

## 62) What is the use of a Set object in JavaScript?

The JavaScript Set object is used to store the elements with unique values. The values can be of any type i.e. whether primitive values or object references. For example:

```
1. function display()
2. {
3.     var set = new Set();
4.     set.add("jQuery");
```

```
5. set.add("AngularJS");
6. set.add("Bootstrap");
7. for (let elements of set) {
8.   document.writeln(elements + "<br>");
9. }
10.}
11. display();
```

---

### 63) What is the use of a WeakSet object in JavaScript?

The JavaScript WeakSet object is the type of collection that allows us to store weakly held objects. Unlike Set, the WeakSet are the collections of objects only. It doesn't contain the arbitrary values. For example:

```
1. function display()
2. {
3.   var ws = new WeakSet();
4.   var obj1 = {};
5.   var obj2 = {};
6.   ws.add(obj1);
7.   ws.add(obj2);
8.   //Let's check whether the WeakSet object contains the added object
9.   document.writeln(ws.has(obj1) + "<br>");
10.  document.writeln(ws.has(obj2));
11. }
12. display()
```

---

### 64) What is the use of a Map object in JavaScript?

The JavaScript Map object is used to map keys to values. It stores each element as key-value pair. It operates the elements such as search, update and delete on the basis of specified key. For example:

```
1. function display()
```

```
2. {
3. var map=new Map();
4. map.set(1,"jQuery");
5. map.set(2,"AngularJS");
6. map.set(3,"Bootstrap");
7. document.writeln(map.get(1)+"<br>");
8. document.writeln(map.get(2)+"<br>");
9. document.writeln(map.get(3));
10. }
11. display();
```

---

## 65) What is the use of a WeakMap object in JavaScript?

The JavaScript WeakMap object is a type of collection which is almost similar to Map. It stores each element as a key-value pair where keys are weakly referenced. Here, the keys are objects and the values are arbitrary values. For example:

```
1. function display()
2. {
3. var wm = new WeakMap();
4. var obj1 = {};
5. var obj2 = {};
6. var obj3= {};
7. wm.set(obj1, "jQuery");
8. wm.set(obj2, "AngularJS");
9. wm.set(obj3,"Bootstrap");
10. document.writeln(wm.has(obj2));
11. }
12. display();
```

---

## 66) What are the falsy values in JavaScript, and how can we check if a value is falsy?

Those values which become false while converting to Boolean are called falsy values.

```
1. const falsyValues = ['', 0, null, undefined, NaN, false];
```

We can check if a value is falsy by using the Boolean function or the Double NOT operator (!!).

---

## 67) What do you understand by hoisting in JavaScript?

Hoisting is the default behavior of JavaScript where all the variable and function declarations are moved on top. In simple words, we can say that Hoisting is a process in which, irrespective of where the variables and functions are declared, they are moved on top of the scope. The scope can be both local and global.

### Example 1:

1. hoistedVariable = 12;
2. console.log(hoistedVariable); // outputs 12 even when the variable is declared after it is initialized
3. var hoistedVariable;

### Example2:

1. hoistedFunction(); // Outputs " Welcome to JavaTpoint " even when the function is declared after calling
2. function hoistedFunction(){
3. console.log(" Welcome to JavaTpoint ");
4. }
5. Example3:
6. // Hoisting in a local scope
7. function doSomething(){
8. x = 11;
9. console.log(x);
10. var x;
11. }
12. doSomething(); // Outputs 11 since the local variable "x" is hoisted inside the local scope

# ES6 Interview Questions

A list of frequently asked **ES6 Interview Questions** and Answers are given below.

## 1) What is ES6 or ECMAScript 2015?

ES6 was released in June 2015, which is stated as the sixth edition of the language. Initially, it was named **ES6** and later renamed to ECMAScript 2015. This edition includes several new features that are modules, iterators, class, arrow functions, for...of loop, promises, and many more. Brendan Eich developed it.

---

## 2) Define ECMAScript.

It is the specification that is defined in the ECMA-262 standard to create a general-purpose scripting language.

---

## 3) What are the new features introduced in ES6?

The new features that are introduced in ES6 are listed as follows:

- Let and const keywords.
  - Default Parameters.
  - Arrow functions.
  - Template Literals.
  - Object Literals.
  - Rest and spread operators.
  - Destructuring assignment.
  - Modules, Classes, Generators, and iterators.
  - Promises, and many more.
- 

## 4) Define let and const keywords.

**let:** The variables declared using **let** keyword will be mutable, i.e., the values of the variable can be changed. It is similar to **var** keyword except that it provides block scoping.

**const:** The variables declared using **the const** keyword are immutable and block-scoped. The value of the variables cannot be changed or re-assigned if they are declared by using **the const** keyword.

---

## 5) What is the arrow function, and how to create it?

Arrow functions are introduced in **ES6**. Arrow functions are the shorthand notation to write **ES6 functions**. The definition of the arrow function consists of parameters, followed by an arrow (=>) and the body of the function.

An Arrow function is also called as '**fat arrow**' function. We cannot use them as constructors.

### Syntax

1. **const** functionName = (arg1, arg2, ...) => {
  2.    //body of the function
  3. }
- 

## 6) Give an example of an Arrow function in ES6? List down its advantages.

Arrow function provides us a more accurate way of writing the **functions in JavaScript**. They allow us to write smaller function syntax.

The context within the arrow functions is lexically or statically scoped. Arrow functions do not include any prototype property, and cannot be used with the new keyword.

You can learn more about arrow functions by clicking on this link [ES6 Arrow Function](#).

### Example

1. var myfun = () => {

```
2. console.log("It is an Arrow Function");
3. };
4. myfun();
```

### Output

```
It is an Arrow Function
```

### Advantages of Arrow Function

The advantages of the arrow function are listed below:

- It reduces code size.
- The return statement is optional for a single line function.
- Lexically bind the context.
- Functional braces are optional for a single-line statement.

---

## 7) Discuss spread operator in ES6 with an example.

The spread operator is represented by three dots (...) to obtain the list of parameters. It allows the expansion of an iterable such as array or string in places where more than zero arguments are expected.

The spread operator syntax is similar to the rest operator, but functionality is entirely opposite to it. It is also used to combine or to perform the concatenation between arrays. Let's understand it by an example.

### Example

```
1. let num1 = [40,50,60];
2.
3. let num2 = [10,20,30,...num1,70,80,90,100];
4.
5. console.log(num2);
```

### Output

```
[
```

```
10, 20, 30, 40, 50,  
60, 70, 80, 90, 100  
]
```

---

## 8) Discuss the Rest parameter in ES6 with an example.

It is introduced in ES6 that improves the ability to handle the parameters. With rest parameters, it is possible to represent indefinite parameters as an array. By using the rest parameter, we can call a function with any number of arguments.

### Example

```
1. function show(...args) {  
2.   let sum = 0;  
3.   for (let i of args) {  
4.     sum += i;  
5.   }  
6.   console.log("Sum = "+sum);  
7. }  
8.  
9. show(10, 20, 30);
```

### Output

```
Sum = 60
```

---

## 9) What are the template literals in ES6?

Template literals are a new feature introduced in ES6. It provides an easy way of creating multiline strings and perform string interpolation.

Template literals allow embedded expressions and also called as string literals.

Prior to ES6, template literals were referred to as **template strings**. Template literals are enclosed by the **backtick (` ) character**. Placeholders in template literals are represented by the dollar sign and the curly braces (**`\${expression}`**). If we require to use an expression within the backticks, then we can place that expression in the **`\${expression}`**.

To learn more about template literals in ES6, follow this link [ES6 Template Literals](#).

### Example

1. let str1 = "Hello";
- 2.
3. let str2 = "World";
- 4.
5. let str = `\${str1} \${str2}`;
6. console.log(str);

### Output

```
Hello World
```

---

## 10) Discuss Destructuring Assignment in ES6.

Destructuring is introduced in ECMAScript 2015 or ES6 to extract data from objects and arrays into separate variables. It allows us to extract smaller fragments from objects and arrays.

To learn more about array destructuring in ES6, follow this link [ES6 Array Destructuring](#).

To learn more about object destructuring in ES6, follow this link [ES6 Object Destructuring](#).

### Example

1. let fullname =['Alan','Rickman'];
2. let [fname,lname] = fullname;
3. console.log (fname,lname);

### Output

```
Alan Rickman
```

---

## 11) How to create a class in ES6?

This keyword is used for creating the class. We can include the classes in our code either by using class expression or by class declaration. A class definition can only include **functions** and **constructors**. These components are together called as data members of the class.

Constructors in classes allocate the memory to the objects of the class. Functions in a class are responsible for performing the actions to the objects.

To learn more about classes in ES6, follow this link [ES6 Classes](#).

Let us see the syntax for creating classes.

### Syntax: In ES5

1. var var\_name = **new** class\_name {
2. }

### Syntax: In ES6 (Using class keyword)

1. **class** class\_name{
  2. }
- 

## 12) What do you understand by Generator function?

A generator provides us a new way to work with iterators and functions. The generator is a special kind of function that may be paused in the middle either one or many times and can be resumed later. The declaration **function\* (function keyword followed by an asterisk)** is used to define a generator function.

When the generator gets called, it does not run its code. Instead, it returns a special object, which is called a **Generator object** to manage the execution. Let us see an example of generators in ES6.

To learn more about Generators in ES6, follow this link [ES6 Generators](#).

### Example

1. function\* gen()
2. {

```
3. yield 100;
4. yield;
5. yield 200;
6. }
7. // Calling the Generator Function
8. var mygen = gen();
9. console.log(mygen.next().value);
10. console.log(mygen.next().value);
11. console.log(mygen.next().value);
```

### Output

```
100
undefined
200
```

---

## 13) What are the default parameters?

By using the default parameters, we can initialize named parameters with default values if there is no value or **undefined** is passed.

### Example

```
1. var show = (a, b=200) => {
2.   console.log(a + " " + b);
3. }
4. show(100);
```

### Output

```
100 200
```

---

## 14) What do you mean by IIFE (Immediately invoked function expressions)?

IIFE is a function in JavaScript that runs as soon as it is defined. It is also called as the **Self-Executing Anonymous Function**. It includes two major parts that are as follows:

- The first part is an anonymous function that has a lexical scope (static scope), which is enclosed within the **Grouping operator ()**.
- The second part creates the IIFE by which the **JavaScript** engine will interpret the function directly.

You can learn more about arrow functions by clicking on this link [ES6 IIFE](#).

### Example

```
1. (function()
2. {
3.   console.log("Hello World");
4. })();
```

### Output

```
Hello World
```

## 15) Discuss the for...in loop.

It is similar to for loop that iterates through the properties of an object. It is useful when we require to visit the properties or keys of the object.

### Example

```
1. function Mobile(model_no){
2.   this.Model = model_no;
3.   this.Color = 'White';
4.   this.RAM = '4GB';
5. }
6. var Samsung = new Mobile("Galaxy");
7. for(var props in Samsung)
8. {
9.   console.log(props+ " : " +Samsung[props]);
10. }
```

### Output

```
Model: Galaxy  
Color: White  
RAM: 4GB
```

---

## 16) Discuss the for...of loop.

This loop is used for iterating the iterables (arrays, string, etc.).

### Example

1. var fruits = ['Apple', 'Banana', 'Mango', 'Orange'];
2. **for**(let value of fruits)
3. {
4. console.log(value);
5. }

### Output

```
Apple  
Banana  
Mango  
Orange
```

---

## 17) Define set.

A set is a data structure that allows us to create a collection of unique values. It is a collection of values that are similar to arrays, but it does not include any duplicates. It supports both object references and primitive values.

To learn more about Sets in ES6, follow this link [ES6 Sets](#).

### Example

1. let colors = **new** Set(['Green', 'Red', 'Orange', 'Yellow', 'Red']);
2. console.log(colors);

### Output

```
Set { 'Green', 'Red', 'Orange', 'Yellow' }
```

---

## 18) Define Map.

Prior to ES6, when we require the mapping of keys and values, we often use an object. **Map object** is a new collection type, which is introduced in ES6. It holds the key-value pairs in which any type of values can be used as either keys or values.

A map object always remembers the actual insertion order of the keys. Maps are ordered, so they traverse the elements in their insertion order.

To learn more about Map in ES6, follow this link [ES6 Maps](#).

---

## 19) What do you understand by Weakset?

Using weakset, it is possible to store weakly held objects in a collection. As similar to set, weakset cannot store duplicate values. Weakset cannot be iterated.

Weakset only includes **add(value)**, **delete(value)** and **has(value)** methods of the set object.

---

## 20) What do you understand by Weakmap?

Weak maps are almost similar to maps, but the keys in weak maps must be objects. It stores each element as a key-value pair where keys are weakly referenced. Here, the keys are objects, and the values are arbitrary.

A weak map object iterates the element in their insertion order. It only includes **delete(key)**, **get(key)**, **has(key)** and **set(key, value)** method.

---

## 21) Explain Promises in ES6.

ES6 promises are the easiest way to work with asynchronous programming in JavaScript. Asynchronous programming includes running of processes individually from the main thread, and it notifies the main thread when it gets complete.

Prior to ES6, there is the use of **Callbacks** for performing asynchronous programming. Promises are used to overcome the problem of **Callback hell**.

To learn more about promises, follow this link: [ES6 Promises](#).

---

## 22) What are the states of promises in ES6?

Promises have mainly three states that are as follows:

- **Pending:** It is the initial state of every promise. It represents that the result has not been computed yet.
- **Fulfilled:** It represents the completion of an operation.
- **Rejected:** It represents the failure that occurs during computation.

Once the promise is fulfilled or rejected, then it will be immutable. The **Promise()** constructor takes two arguments that are **rejected** function and a **resolve** function. Based on the asynchronous operation, it returns either the first argument or the second argument.

---

## 23) What do you understand by Callback and Callback hell in JavaScript?

**Callback:** It is used to handle the execution of function after the completion of the execution of another function. A callback would be helpful in working with events. In the callback, a function can be passed as an argument to another function. It is a great way when we are dealing with basic cases such as minimal asynchronous operations.

**Callback hell:** When we develop a web application that includes a lot of code, then working with callback is messy. This excessive Callback nesting is often referred to as **Callback hell**.

---

## 24) List the comparisons between ES5 and ES6.

ES5 and ES6 are similar in their nature, but there are some differences between them. The comparison between ES5 and ES6 are tabulated as follows:

Based on	ES5	ES6
<b>Definition</b>	ES5 is the fifth edition of the ECMAScript (a trademarked scripting language specification defined by ECMA International)	ES6 is the sixth edition of the ECMAScript (a trademarked scripting language specification defined by ECMA International).
<b>Release</b>	It was introduced in 2009.	It was introduced in 2015.
<b>Data-types</b>	ES5 supports primitive data types that are <b>string</b> , <b>boolean</b> , <b>number</b> , <b>null</b> , and <b>undefined</b> .	In ES6, there are some additions to JavaScript data types. It introduced a new primitive data type ' <b>symbol</b> ' for supporting unique values.
<b>Defining Variables</b>	In ES5, we could only define the variables by using the <b>var</b> keyword.	In ES6, there are two new ways to define variables that are <b>let</b> and <b>const</b> .
<b>Performance</b>	As ES5 is prior to ES6, there is a non-presence of some features, so it has a lower performance than ES6.	Because of new features and the shorthand storage implementation ES6 has a higher performance than ES5.
<b>Support</b>	A wide range of communities supports it.	It also has a lot of community support, but it is lesser than ES5.
<b>Object Manipulation</b>	ES5 is time-consuming than ES6.	Due to destructuring and spread operators, object manipulation can be processed more smoothly in ES6.
<b>Arrow Functions</b>	In ES5, both <b>function</b> and <b>return</b> keywords are used to define a function.	An arrow function is a new feature introduced in ES6 by which we don't require the <b>function</b> keyword to define the function.
<b>Loops</b>	In ES5, there is a use of <b>for</b> loop to iterate over elements.	ES6 introduced the concept of <b>for...of</b> loop to perform an iteration over the values of the iterable objects.

To learn more about the difference between ES5 and ES6, follow this link: [ES5 v/s ES6](#)

---

## 25) Define Modules in JavaScript.

Modules are the piece of JavaScript code written in a file. By using Modules, it is easy to maintain the code, debug the code, and reuse the code. Each module is a piece of code that gets executed once it is loaded.

---

## 26) What do you understand by the term Hoisting in JavaScript?

It is a JavaScript's default behavior, which is used to move all the declarations at the top of the scope before the execution of code. It can be applied to functions as well as on variables. It allows the JavaScript to use the component before its declaration. It does not apply to scripts that run in strict mode.

---

## 27) List the new Array methods introduced in ES6?

There are many array methods available in ES6, which are listed below:

- `Array.of()`
- `Array.from()`
- `Array.prototype.copyWithin()`
- `Array.prototype.find()`
- `Array.prototype.findIndex()`
- `Array.prototype.entries()`
- `Array.prototype.keys()`
- `Array.prototype.values()`
- `Array.prototype.fill()`

To learn more about the above array methods, follow this link: [ES6 Array methods](#).

---

## 28) What are the new String methods introduced in ES6?

There are four string methods introduced in ES6 that are listed as follows:

- o `string.startsWith()`
- o `string.endsWith()`
- o `string.includes()`
- o `string.repeat()`

To learn more about the strings, follow this link: [ES6 Strings](#).

---

## 29) Define Babel.

Babel is one of the popular transpilers of JavaScript. It is mainly used for converting the ES6 plus code into the backward-compatible version of JavaScript that can be run by previous JavaScript engines.

---

## 30) Define Webpack.

It is an open-source JavaScript module bundler that takes modules with dependencies. It allows us to run an environment that hosts Babel.

Component	Bootstrap 3	Bootstrap 4
Big Change	-	<b>Flexbox</b>
CSS preprocessors	<b>LESS</b> LESS is JavaScript based	<b>SCSS</b> Sass is Ruby based
Grid System	<b>4 Columns</b> (xs, sm, md, lg)	<b>5 Columns</b> (xs, sm, md, lg, xl)
Glyphicon	<b>Supported</b>	<b>Not Supported</b>
Primary CSS Unit	<b>px</b>	<b>rem</b>
Global Font Size	<b>14px</b>	<b>16px</b>
Dropdown Structure	<b>Created with ul and li</b>	<b>Created with ul or div</b>
Offsetting Columns	<b>col-md-offset-4</b>	<b>offset-md-4</b>
Images	<b>.img-responsive</b>	<b>.img-fluid</b>

## Container Class with different Break Points

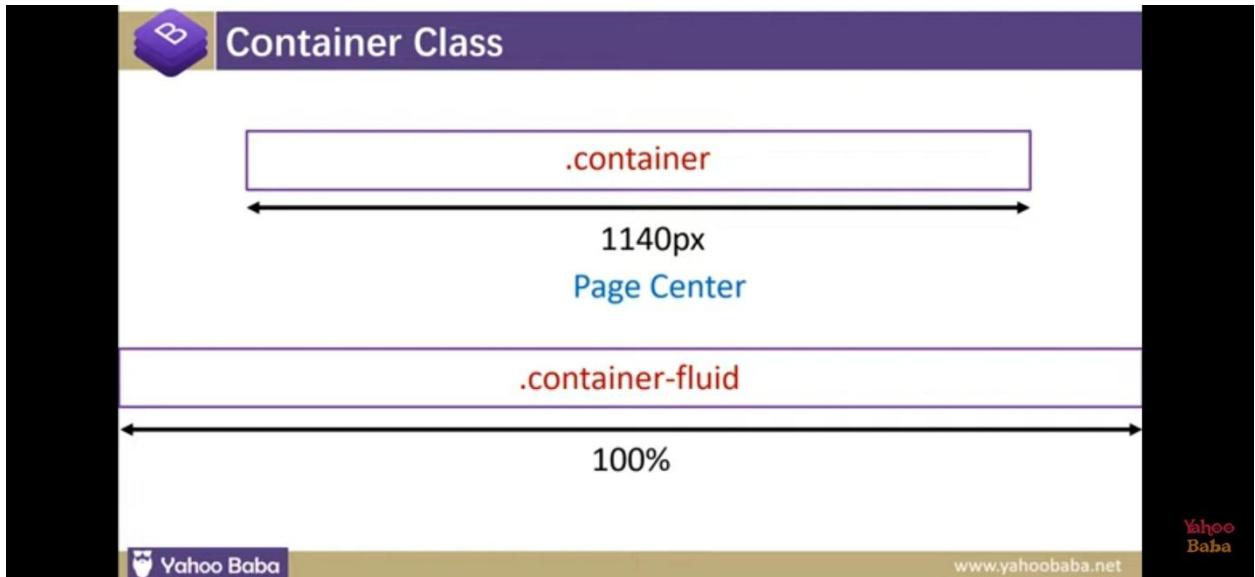

**Container Width**

Extra Large	>= 1200px	1140px
Large	>= 992px	960px
Medium	>= 768px	720px
Small	>= 576px	540px
Extra Small	< 576px	Auto

Yahoo Baba
 

[www.yahooibaba.net](http://www.yahooibaba.net)

 Yahoo Baba

**Container Class with different Break Points**

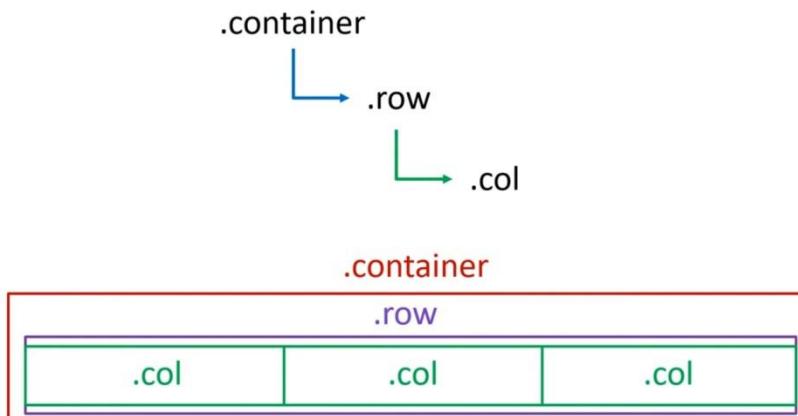

The table defines five responsive container widths based on screen size break points:

Container Width		
Extra Large	$\geq 1200\text{px}$	1140px
Large	$\geq 992\text{px}$	960px
Medium	$\geq 768\text{px}$	720px
Small	$\geq 576\text{px}$	540px
Extra Small	$< 576\text{px}$	Auto

Both the top and bottom sections include the **Yahoo Baba** logo and the URL [www.yahooibaba.net](http://www.yahooibaba.net).

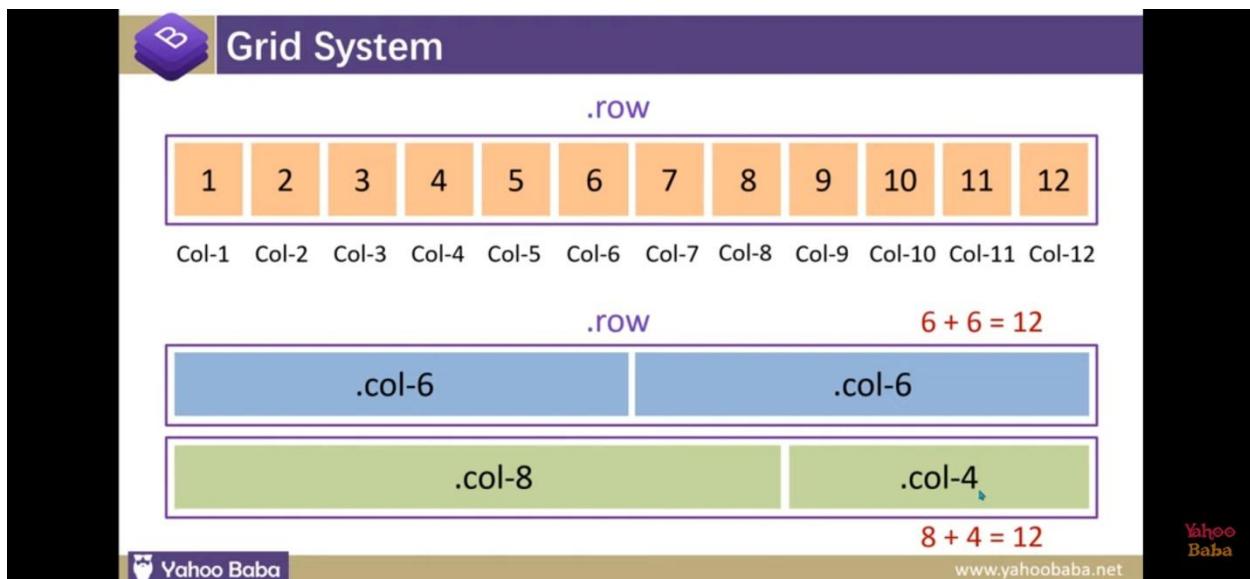

## Layout Classes Sequence

## Different Position Values

- 1). Relative
- 2). Absolute
- 3). Fixed
- 4). Sticky
- 5). Static

The screenshot shows the Bootstrap v5.0 documentation page with the following content:

**Available breakpoints**

Bootstrap includes six default breakpoints, sometimes referred to as *grid tiers*, for building responsively. These breakpoints can be customized if you're using our source Sass files.

Breakpoint	Class infix	Dimensions
X-Small	<i>None</i>	0-576px
Small	<i>sm</i>	$\geq 576px$
Medium	<i>md</i>	$\geq 768px$
Large	<i>lg</i>	$\geq 992px$
Extra large	<i>xl</i>	$\geq 1200px$
Extra extra large	<i>xxl</i>	$\geq 1400px$

Each breakpoint size was chosen to be a multiple of 12 and to be representative of a subset of common device sizes and viewport dimensions. They don't specifically target every use case or device type.

## Padding Classes for different Break Points

	Padding	Padding-right	Padding-left	Padding-top	Padding-bottom
Extra Large	.p-xl-*	.pr-xl-*	.pl-xl-*	.pt-xl-*	.pb-xl-*
Large	.p-lg-*	.pr-lg-*	.pl-lg-*	.pt-lg-*	.pb-lg-*
Medium	.p-md-*	.pr-md-*	.pl-md-*	.pt-md-*	.pb-md-*
Small	.p-sm-*	.pr-sm-*	.pl-sm-*	.pt-sm-*	.pb-sm-*
Extra Small					

0 - 5

## About CSS Flexbox :

- New module in CSS3 to easily align elements in different directions and orders
- Flexbox gives container the ability to expand and shrink elements to best use all the available space
- CSS Flexbox Layout replaces float layout
- New way to build one-dimensional layouts

The screenshot shows a code editor interface with the following details:

- EXPLORER** sidebar on the left containing files: fonts, images (1.jpg, 2.png, 3.png, 4.png), arrow.png, object.jpg, sprite.png, index.html, and style.css.
- OPEN EDITORS** section showing "style.css" is open.
- Editor Area:**

```
# style.css > {} @media screen and (min-width: 400px) and (max-width: 768px){  
16  
17     #div1{  
18         width: 50%;  
19     }  
20     #div2{  
21         width: 50%;  
22     }  
23 }  
24  
25 @media screen and (min-width: 400px) and (max-width: 768px){  
26     #div1{  
27         width: 100%;  
28     }  
29     #div2{  
30         width: 100%;  
31         color: white;  
32         background-color: black;  
33     }  
34 }  
35 }
```
- Bottom Right Corner:** TECHGUN logo.

The screenshot shows a code editor interface with the following details:

- EXPLORER** sidebar on the left containing files: fonts, images (1.jpg, 2.png, 3.png, 4.png), arrow.png, object.jpg, sprite.png, index.html, and style.css.
- OPEN EDITORS** section showing "style.css" is open.
- Editor Area:**

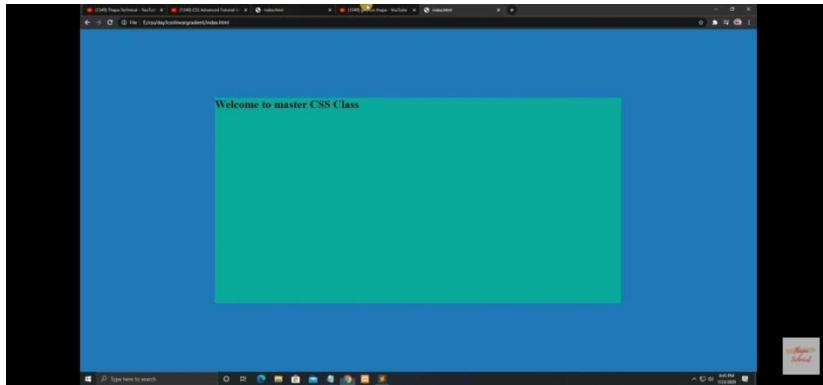

```
# style.css > video  
26     @media screen and (min-width: 400px) and (max-width: 768px){  
27         #div1{  
28             width: 100%;  
29         }  
30         #div2{  
31             width: 100%;  
32             color: white;  
33             background-color: black;  
34         }  
35     }  
36  
37     img{  
38         width: 100%;  
39         height: auto;  
40     }  
41  
42     video{  
43         width: 100%;  
44         height: auto;}
```
- Bottom Right Corner:** TECHGUN logo.

The screenshot shows the 'Can I use...' website interface. At the top, it displays 'July 18, 2018 - New feature: Shared Array Buffer'. Below this, there's a section titled 'CSS Grid Layout' with a brief description: 'Method of using a grid concept to lay out content, providing a mechanism for authors to divide available space for layout into columns and rows using a set of predictable sizing behaviors. Includes support for all `grid-`\* properties and the `fr` unit.' To the right, there's a statistics panel showing usage percentages: Global (84.53% + 3.2% = 87.73%) and unprefixed (84.53%). Below the description is a table showing browser support and usage percentages. The table includes columns for IE, Edge, Firefox, Chrome, Safari, iOS Safari, Opera Mini, Chrome for Android, UC Browser for Android, and Samsung Internet. The 'grid-template-columns' row shows values like 49%, 66%, 10.3%, etc. The 'grid-template-rows' row shows values like 11, 17, 61, 68, 11.1, 11.4, etc. The 'grid-template-areas' row shows values like 18, 62, 69, 12, 12, etc. The 'grid-template' row shows values like 63, 70, TP, etc.

## CSS Grid Properties:

- `grid-template-rows`

Quickest ways to Center Div

A red circle containing a white phone icon is centered on the page.

A screenshot of a code editor and a browser window. The code editor on the left shows a file named 'index.html' with the following CSS:

```
31 }
32 .example-div {
33   background: url("logo_large.png") #cc0000 no-repeat;
34   background-size: 100%;
35   width: 200px;
36   height: 200px;
37   border-radius: 50%;
38   position: absolute;
39   top: 50%;
40   left: 50%;
41   transform: translate(-50%, -50%);
42 }
43 .parent-div {
44   /* nothing */
45 }
```

The browser window on the right displays a red circular background with a white logo in the center, titled "Quickest ways to Center Div". Below the browser is a text overlay: "center of the screen and will ignore all other elements very useful if you want".

A screenshot of a code editor showing a file named 'center.html'. The code uses flexbox to center a div:

```
4 <meta charset="utf-8">
5 <title></title>
6 <style type="text/css">
7   body, html{
8     width: 100%;
9     height: 100%;
10    margin: 0;
11    padding: 0;
12    display: flex;
13    justify-content: center;
14    align-items: center;
15  }
16  #box_outer{
17    width: 300px;
18    height: 300px;
19    background: violet;
20  }
21 </style>
22 </head>
23 <body>
24 <div id="box_outer">
25
26 </div>
```

A screenshot of a code editor showing a file named 'center.html'. The code is as follows:

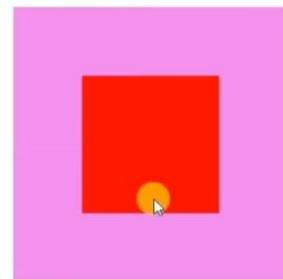

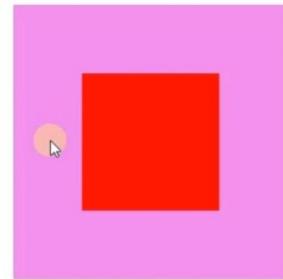

```
13 justify-content: center;
14 align-items: center;
15 }
16 #box_outer{
17     width: 300px;
18     height: 300px;
19     background: violet;
20     position: relative;
21 }
22 #box_inner{
23     width: 150px;
24     height: 150px;
25     background: red;
26     position: absolute;
27     top: 0;
28     left: 0;
29     bottom: 0;
30     right: 0;
31     margin: auto; |
```

A screenshot of a code editor showing the same file 'center.html' with a modification at line 28:

```
13 justify-content: center;
14 align-items: center;
15 }
16 #box_outer{
17     width: 300px;
18     height: 300px;
19     background: violet;
20     position: relative;
21 }
22 #box_inner{
23     width: 150px;
24     height: 150px;
25     background: red;
26     position: absolute;
27     top: 50%;
28     left: 50%; |
```

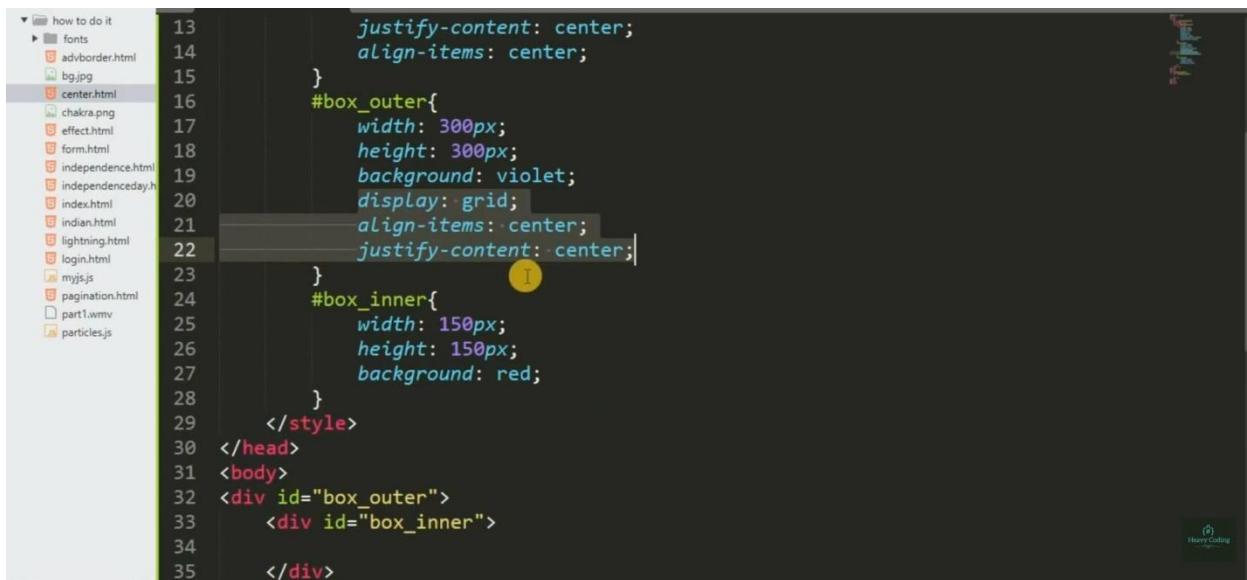

The cursor is at the end of the line 'left: 50%;'. A yellow circle highlights the 't' in 'translate' and the '50%' values.

```
29     transform: translate(-50%, -50%);
```

```
13     justify-content: center;
14     align-items: center;
15   }
16   #box_outer{
17     width: 300px;
18     height: 300px;
19     background: violet;
20     display: grid;
21     place-content: center;
22   }
23   #box_inner{
24     width: 150px;
25     height: 150px;
26     background: red;
27   }
28 </style>
29 </head>
30 <body>
31 <div id="box_outer">
32   <div id="box_inner">
33
34   </div>
35 </div>
```

```
13     justify-content: center;
14     align-items: center;
15   }
16   #box_outer{
17     width: 300px;
18     height: 300px;
19     background: violet;
20     display: grid;
21     align-items: center;
22     justify-content: center;
23   }
24   #box_inner{
25     width: 150px;
26     height: 150px;
27     background: red;
28   }
29 </style>
30 </head>
31 <body>
32 <div id="box_outer">
33   <div id="box_inner">
34   </div>
35 </div>
```

Bootstrap 5 first alpha was officially released on June 16, 2020.

---

Summary of the most important changes:

- jQuery was removed
- Switch to Vanilla JavaScript
- Drop Internet Explorer 10 and 11 support
- Improved grid system
- Improved documentation
- Improved modularity
- Improved forms
- New responsive font
- New utilities & helpers
- Easier customization & theming
- Lighter package
- New API available

## About CSS Flexbox :

- New module in CSS3 to easily align elements in different directions and orders
- Flexbox gives container the ability to expand and shrink elements to best use all the available space
- CSS Flexbox Layout replaces float layout
- New way to build one-dimensional layouts

## Justify-content Values:

### Horizontal Alignment

- flex-start
- flex-end
- center
- space-around
- space-between
- space-evenly

## CSS Flex-direction values:

- row
  - row-reverse
  - column
  - column-reverse

### Align-items Values:

- flex-start
  - flex-end
  - center
  - stretch
  - baseline

# Vertical Alignment

<b>Rows - Grid System</b>	<b>Typography</b>	<b>Tables</b>
Rows are in .container or .container-fluid	.h1 .h2 .h3 .h4 .h5 .h6 .small <small> .lead @font-size-base   @line-height-base	.table .table-striped .table-bordered .table-hover .table-condensed .table-responsive

# Bootstrap 3 CSS Classes

## Desk Reference

1/8

### Grid

**Basic grid - full width is 12 columns wide**

```
<!-- change .container to .container-fluid to be full width -->
<div class="container">
  <!-- Columns are always 50% wide, on mobile and desktop -->
  <div class="row">
    <div class="col-xs-6">.col-xs-6</div>
    <div class="col-xs-6">.col-xs-6</div>
  </div>
  <!-- nested columns example -->
  <div class="row">
    <div class="col-xs-6">.col-xs-6</div>
    <div class="col-xs-6">.col-xs-6
      <div class="row">
        <div class="col-md-6">100% mobile 50% everywhere else</div>
        <div class="col-md-6">100% mobile 50% everywhere else</div>
      </div>
    </div>
  </div>
</div>
```

#### Media queries

```
/* Extra small devices (phones, less than 768px) No media query since this is the default in Bootstrap */
/* small (tablets, 768px and up) */
@media (min-width: @screen-sm-min) { ... }
/* medium (desktops, 992px and up) */
@media (min-width: @screen-md-min) { ... }
/* large (large desktops, 1200px and up) */
@media (min-width: @screen-lg-min) { ... }
```

### Text & Images

.text-left Left aligned text  
.text-center Center aligned text  
.text-right Right aligned text  
.text-justify Justified text  
.text nowrap No wrap text  
.text-lowercase Lowercase text  
.text-uppercase Uppercase text  
.text-capitalize Capitalized text  
.lead Good for first paragraph of article  
.list-unstyled Removes default list margin/padding  
.list-inline Makes list items inline  
.dl-horizontal Makes list items two columns  
.img-responsive Make an image responsive  
.img-rounded Adds rounded corners to image  
.img-circle Crops image to be circle  
.img-thumbnail Adds rounded corner and border to an image  
.pull-left Floats item left  
.pull-right Floats item right  
.center-block Set an element to block with auto left and right margin  
.clearfix Clear floats by adding this class to the parent container

#### Blockquote

```
<blockquote><p>Lorem ipsum dolor</p>
<footer>Someone famous in <cite title="Source Title">Source Title</cite></footer></blockquote>
```

#### Headings

```
<h1>h1. Bootstrap heading <small>Secondary text</small></h1>
<p class="h1">Paragraph that looks like heading</p>
```

## Navbar

```
<!-- Fixed top navbar with brand as logo image tags -->
<nav class="navbar navbar-default navbar-fixed-top">
  <div class="container-fluid">
    <!-- Brand and toggle get grouped for better mobile display -->
    <div class="navbar-header">
      <button type="button" class="navbar-toggle collapsed" data-toggle="collapse" data-target="#bs-example-navbar-collapse-1" aria-expanded="false">
        <span class="sr-only">Toggle navigation</span>
        <span class="icon-bar"></span>
        <span class="icon-bar"></span>
        <span class="icon-bar"></span>
      </button>
      <a class="navbar-brand" href="#"></a>
    </div>
    <!-- Collect the nav links, forms, and other content for toggling -->
    <div class="collapse navbar-collapse" id="bs-example-navbar-collapse-1">
      <ul class="nav navbar-nav">
        <li class="active"><a href="#">Link <span class="sr-only">(current)</span></a></li>
        <li><a href="#">Link</a></li>
        <li class="dropdown">
          <a href="#" class="dropdown-toggle" data-toggle="dropdown" role="button" aria-haspopup="true" aria-expanded="false">Dropdown <span class="caret"></span></a>
          <ul class="dropdown-menu">
            <li><a href="#">Action</a></li>
            <li role="separator" class="divider"></li>
            <li><a href="#">Separated link</a></li>
          </ul>
        </li>
      </ul>
    </div><!-- /.navbar-collapse -->
  </div><!-- /.container-fluid -->
</nav>
```

# Bootstrap 3 CSS Classes

Desk Reference

## Forms

```
<form>
  <div class="form-group">
    <label for="exampleInputEmail1">Email address</label>
    <input type="email" class="form-control" id="exampleInputEmail1" placeholder="Email">
  </div>
  <div class="form-group">
    <label for="exampleInputPassword1">Password</label>
    <input type="password" class="form-control" id="exampleInputPassword1" placeholder="Password">
  </div>
  <div class="form-group">
    <label for="exampleInputFile">File input</label>
    <input type="file" id="exampleInputFile">
    <p class="help-block">Example block-level help text here.</p>
  </div>
  <div class="checkbox">
    <label>
      <input type="checkbox"> Check me out
    </label>
  </div>
  <button type="submit" class="btn btn-default">Submit</button>
</form>
```

## Buttons

.btn Needs to be added to all buttons because it adds padding and margin  
.btn-default The default button style  
.btn-primary The button that has the primary action in a group  
.btn-success Could be used on the last submit button in a form  
.btn-info Informational button  
.btn-link Removes background color and add text color  
.btn-lg Large button  
.btn-sm Smaller than default button  
.btn-xs Even smaller  
.btn-block Button that spans full width of parent

```
<a class="btn btn-default" href="#" role="button">Link</a>
<button class="btn btn-primary" type="submit">Button</button>
```

### Carousel

```
<div id="carousel-example-generic" class="carousel slide" data-ride="carousel">
  <!-- Indicators -->
  <ol class="carousel-indicators">
    <li data-target="#carousel-example-generic" data-slide-to="0" class="active"></li>
    <li data-target="#carousel-example-generic" data-slide-to="1"></li>
  </ol>
  <!-- Wrapper for slides -->
  <div class="carousel-inner" role="listbox">
    <div class="item active">
      
      <div class="carousel-caption">
        ...
      </div>
    </div>
    <div class="item">
      
      <div class="carousel-caption">
        ...
      </div>
    </div>
    ...
  </div>
  <!-- Controls -->
  <a class="left carousel-control" href="#carousel-example-generic" role="button" data-slide="prev">
    <span class="glyphicon glyphicon-chevron-left" aria-hidden="true"></span>
    <span class="sr-only">Previous</span>
  </a>
  <a class="right carousel-control" href="#carousel-example-generic" role="button" data-slide="next">
    <span class="glyphicon glyphicon-chevron-right" aria-hidden="true"></span>
    <span class="sr-only">Next</span>
  </a>
</div>
```

5/8

## Jumbotron

```
<div class="jumbotron">
  <h1>Hello, world!</h1>
  <p>...</p>
  <p><a class="btn btn-primary btn-lg" href="#" role="button">Learn more</a></p>
</div>
```

To make the jumbotron full width, and without rounded corners, place it outside all .containers and instead add a .container within.

```
<div class="jumbotron">
  <div class="container">
    ...
  </div>
</div>
```

## Page header

```
<div class="page-header">
  <h1>Example page header <small>Subtext for header</small></h1>
</div>
```

## Breadcrumbs

```
<ol class="breadcrumb">
  <li><a href="#">Home</a></li>
  <li><a href="#">Library</a></li>
  <li class="active">Data</li>
</ol>
```

## Responsive embed

```
<!-- 16:9 aspect ratio - change aspect ratio by replacing 16by9 with 4by3 -->
<div class="embed-responsive embed-responsive-16by9">
  <iframe class="embed-responsive-item" src="..."></iframe>
</div>
```

## Cheat Sheet [TAGS]

New [tags added in HTML5]				Old [unsupported tags]			
<article>	self-contained composition that is independently distributable	<details>	details of an element	<output>	represents results of calculation	<acronym>	acronym
<aside>	section of page that consists of content tangentially related to content around it	<embed>	embedded content	<progress>	progress of any kind of task	<applet>	applet
<audio>	sound content	<figcaption>	caption of figure element	<rp>	parenthesized ruby text	<basefont>	base font
<bdi>	span of text to be isolated from surroundings for bidirectional formatting purposes	<figure>	group of media content	<rt>	ruby text	<bgsound>	background sound
<canvas>	area that can be used to draw graphics via JavaScript	<header>	header for section or page	<ruby>	ruby annotations	<big>	big text
<command>	user invokable command	<hgroup>	group of headings for section	<section>	section in a document	<center>	centered text
<datalist>	dropdown list	<keygen>	generated key in a form	<source>	media resources	<fn>	footnotes
<datatemplate>	data template	<mark>	marked text	<summary>	header of a detail element	<font>	text font, size, and color
		<meter>	measurement in defined range	<time>	datetime	<frame>	sub window
		<video>	video	<wbr>	possible line break	<frameset>	set of frames
Existing [tags in HTML4 & 5]							
<!---->	comment	<code>	code text	<html>	html document	<object>	embedded object
<!doctype>	document type	<col>	attributes for columns	<i>	italic text	<ol>	ordered list
<a>	hyperlink	<colgroup>	groups of columns	<frame>	inline sub window	<optgroup>	option group
<abbr>	abbreviation	<dd>	definition description	<img>	image	<option>	option in a drop-down list
<address>	address element	<del>	deleted text	<input>	input field	<p>	paragraph
<area>	image map area	<div>	generic block-level element	<ins>	inserted text	<param>	parameter for an object
<b>	bold text	<dfn>	defining instance of a term	<kbd>	keyboard text	<pre>	preformatted object
<base>	base URL for all links in page relative to document root	<dl>	definition list	<label>	label for a form control	<q>	short quotation
<bdo>	text direction	<dt>	definition term	<legend>	title in a fieldset	<samp>	sample computer code
<blockquote>	long quotation	<em>	emphasized text	<li>	list item	<script>	script
<body>	body element	<fieldset>	logically group items in a form	<link>	resource reference	<select>	selectable list
 	single line break	<form>	defines a form	<map>	image map	<small>	small text
<button>	push button	<h1> to <h6>	header 1 to header 6	<menu>	menu list	<span>	inline generic container
<caption>	table caption	<head>	document information	<meta>	meta information	<strong>	strong text
<cite>	citation	<hr>	horizontal rule	<noscript>	no script section	<style>	style definition

HTML 5 NEW TAG	
TAG NOT SUPPORTED IN HTML 5	
<!--><!--&gt;</td> <td>Define a comment</td>	Define a comment
<!DOCTYPE>	Defines the document type
<a>	Defines a hyperlink href, hreflang, media, ping, rel, target, type
<abbr>	Defines an abbreviation
<acronym>	Used to define an embedded acronym
<address>	Defines an address element
<applet>	Used to define an embedded applet
<area>	Defines an area inside an image map alt, coords, href, hreflang, media, ping, rel, shape, target, type
<article>	Defines an article cite, pubdate
<aside>	Defines content aside from the page content
<audio>	Defines sound content autobuffer, autoplay, controls, src
<b>	Defines bold text
<base>	Defines a base URL for all the links in a page href, target
<basefont>	Used to define a default font-color, font-size, or font-family for all the document
<bdo>	Defines the direction of text display dir
<big>	Used to make text bigger
<blockquote>	Defines a long quotation cite
<body>	Defines the body element
 	Inserts a single line break
<button>	Defines a push button autofocus, disabled, form, formaction, formenctype, formmethod, formnovalidate, formtarget, name, type, value
<canvas>	Defines graphics height, width
<caption>	Defines a table caption
<center>	Used to center align text and content
<cite>	Defines a citation
<code>	Defines computer code text autobuffer, autoplay, controls, src
<col>	Defines attributes for table columns
<colgroup>	Defines groups of table columns span
<command>	Defines a command button checked, disabled, form, label, mediatype, type
<datalist>	Defines a dropdown list
<dd>	Defines a definition description
<del>	Defines deleted text cite, datetime
<details>	Defines details of an element open
<dialog>	Defines a dialog (conversation)
<dfn>	Defines a definition term
<dir>	Used to define a directory list
<div>	Defines a section in a document
<dl>	Defines a definition list
<dt>	Defines a definition term
<em>	Defines emphasized text
<embed>	Defines external interactive content or plugin height, src, type, width
<fieldset>	Defines a fieldset disabled, form, name
<figure>	Defines a group of media content, and their caption
<font>	Used to define font-face, font-size, and font-color of text
<footer>	Defines a footer for a section or page
<form>	Defines a form accept-charset, action, autocomplete, enctype, method, name, novalidate, target
<frame>	Used to define one particular window frame within a frameset
<frameset>	Used to define a frameset, which organizes multiple windows (frames)
<h1> to <h6>	Defines header 1 to header 6
<head>	Defines information about the document
<header>	Defines a header for a section or page
<hgroup>	Defines information about a section in a document
<hr>	Defines a horizontal rule
<html>	Defines an html document manifest, xhtml
<i>	Defines italic text
<iframe>	Defines an inline sub window height, name, sandbox, seamless, src, width
<img>	Defines an image alt, src, height, ismap, usemap, width
<input>	Defines an input field accept, alt, autocomplete, autofocus, checked, disabled, form, formaction, formenctype, formmethod, formnovalidate, formtarget, height, list, max, maxlength, min, multiple, name, pattern, placeholder, readonly, required, size, src, step, type, value, width
<ins>	Defines inserted text cite, datetime
<keygen>	Defines a generated key in a form autofocus, challenge, disabled, form, keytype, name
<kbd>	Defines keyboard text
<label>	Defines an inline sub window for, form
<legend>	Defines a title in a fieldset
<li>	Defines a list item value
<link>	Defines a resource reference href, hreflang, media, rel, sizes, type
<map>	Defines an image map name
<mark>	Defines marked text
<menu>	Defines a menu list label, type
<meta>	Defines meta information charset, content, http-equiv, name
<meter>	Defines measurement within a predefined range high, low, max, min, optimum, value
<nav>	Defines navigation links
<noframes>	Used to display text for browsers that do not handle frames
<noscript>	Defines a noscript section
<object>	Defines an embedded object data, form, height, name, type, usemap, width
<ol>	Defines an ordered list reversed, start
<optgroup>	Defines an option group label, disabled
<option>	Defines an option in a dropdown list disabled, label, selected, value
<output>	Defines some types of output for, form, name
<p>	Defines a paragraph
<param>	Defines a parameter for an object name, value
<pre>	Defines preformatted text
<progress>	Defines progress of a task of any kind max, value
<q>	Defines a short quotation cite
<rp>	Used in ruby annotations to define what to show browsers that do not support the ruby element
<rt>	Defines explanation to ruby annotations
<ruby>	Defines ruby annotations
<s>, <strike>	Used to define strikethrough text.
<script>	Defines sample computer code nsrc, type charset defer, src
<section>	Defines a section cite
<select>	Defines a selectable list autofocus, disabled, form, multiple, name, size
<small>	Defines small text
<source>	Defines media resources media, src, type
<span>	Defines a section in a document
<strong>	Defines strong text
<style>	Defines a style definition type, media, scoped
<sub>, <sup>	Defines sub/super-scripted text
<table>	Defines a table summary
<tbody>	Defines a table body summary
<td>	Defines a table cell colspan, headers, rowspan
<textarea>	Defines a text area autofocus, cols, disabled, form, maxlength, name, placeholder, readonly, required, rows, wrap
<tfoot>, <thead>	Defines a table footer / head
<th>	Defines a table header colspan, headers, rowspan, scope
<time>	Defines a date/time datetime
<title>	Defines the document title
<tr>	Defines a table row datetime
<tt>	Used to define teletype text
<u>	Used to define underlined text
<ul>	Defines an unordered list
<var>	Defines a variable
<video>	Defines a video autobuffer, autoplay, controls, height, loop, src, width

## HTML5 TAG CHEAT SHEET

Created by WebsiteSetup.org

# HTML5 CHEAT SHEET

TAGS	MEANING	TAGS	MEANING	TAGS	MEANING
<a>	hyperlink	<h1>	heading level 1	<progress>	progress of a task
<abbr>	abbreviation	<h2>	heading level 2	<q>	short quotation
<address>	address element	<h2>	heading level 2	<rb>	marks the base text component of a ruby annotation.
<area>	area inside an image map	<h3>	heading level 3	<rp>	used for the benefit of browsers that don't support ruby annotations
<article>	article	<h4>	heading level 4		
		<h5>	heading level 5		
<aside>	content aside from the page content	<h6>	heading level 6	<rt>	ruby text component
<audio>	sound content	<head>	information about the document	<rtc>	marks a ruby text container for ruby text components in a ruby annotation.
<b>	bold text	<header>	group of introductory or navigational aids	<ruby>	ruby annotation
<base>	base URL for all the links in a page	<hr>	horizontal rule	<s>	Indicates text that's no longer accurate or relevant.
<bdi>	bi-directional text formatting	<html>	html document		
<bdo>	direction of text display	<i>	italic text	<samp>	sample computer code
<blockquote>	long quotation	<iframe>	inline sub window (frame)	<script>	script
<body>	body element	<img>	image	<section>	section
 	single line break	<input>	input field	<select>	selectable list
<button>	push button	<ins>	inserted text	<small>	small text
<canvas>	define graphics	<kbd>	keyboard text	<source>	media resources
<caption>	table caption	<keygen>	generates a key pair	<span>	section in a document
<cite>	citation	<label>	label for form control	<strong>	strong text
<code>	computer code text	<legend>	title in afieldset	<style>	style definition
<col>	table columns	<li>	list item	<sub>	subscripted text
<colgroup>	groups of table columns	<link>	resource reference	<summary>	summary / caption for the <details> element
<data>	Allows machine-readable data to be provided	<main>	main content area of an HTML document.	<sup>	superscripted text
<datalist>	"autocomplete" dropdown list	<map>	image map	<table>	table
<dd>	definition description	<mark>	marked text	<tbody>	table body
<del>	deleted text	<menu>	menu list	<td>	table cell
<details>	details of an element	<menuitem>	command that user can invoke from popup menu	<textarea>	text area
				<tfoot>	table footer
<dfn>	definition term	<meta>	meta information	<th>	table header
<dialog>	part of an application is interactive.	<meter>	measurement within a predefined range	<thead>	table header
<div>	section in a document, definition list	<nav>	navigation links	<time>	date/time
<dl>		<noscript>	noscript section	<title>	document title
<dt>	definition term	<object>	embedded object	<tr>	table row
				<track>	text track for media such as video and audio
<em>	emphasized text	<ol>	ordered list	<u>	text with a non-textual annotation.
<embed>	external application or interactive content	<optgroup>	option group	<ul>	unordered list
<fieldset>	fieldset	<option>	option in a drop-down list	<var>	variable
<figcaption>	caption for the figure element.	<output>	types of output	<video>	video
<figure>	group of media content, and their caption	<p>	paragraph	<wbr>	line break opportunity for very long words and strings of text with no spaces.
<footer>	footer section or page	<param>	parameter for an object		
<form>	specifies a form	<pre>	preformatted text		

## 5) What are the advantages of CSS?

- Bandwidth
- Site-wide consistency
- Page reformatting
- Accessibility
- Content separated from presentation

## 6) What are the limitations of CSS?

- Ascending by selectors is not possible
- Limitations of vertical control
- No expressions
- No column declaration
- Pseudo-class not controlled by dynamic behavior
- Rules, styles, targeting specific text not possible

## 10) What are the advantages of Embedded Style Sheets?

- You can create classes for use on multiple tag types in the document.
- You can use selector and grouping methods to apply styles in complex situations.
- No extra download is required to import the information.

## 11) What is a CSS selector?

It is a string that identifies the elements to which a particular declaration applies. It is also referred as a link between the HTML document and the style sheet. It is equivalent of HTML elements. There are several different types of selectors in CSS: -

- CSS Element Selector
- CSS Id Selector
- CSS Class Selector
- CSS Universal Selector

- CSS Group Selector

**24) What is the difference between inline, embedded and external style sheets?**

**28) What is the CSS Box model and what are its elements?**

The CSS box model is used to define the design and layout of elements of CSS.

The elements are:

- Margin - It removes the area around the border. It is transparent.
- Border - It represents the area around the padding
- Padding - It removes the area around the content. It is transparent.
- Content - It represents the content like text, images, etc.

**31) What is the purpose of the z-index and how is it used?**

The z-index helps to specify the stack order of positioned elements that may overlap one another. The z-index default value is zero and can take on either a positive or negative number.

An element with a higher z-index is always stacked above than a lower index.

Z-Index can take the following values:

- **Auto:** Sets the stack order equal to its parents.
- **Number:** Orders the stack order.
- **Initial:** Sets this property to its default value (0).
- **Inherit:** Inherits this property from its parent element.

**32) Explain the difference between visibility: hidden and display: none?**

**visibility: hidden** hides the element, but it occupies space and affects the layout of the document.

**display: none** also hides the element but not occupy space. It will not affect the layout of the document.

### 33) What do you understand by W3C?

W3C stands for World Wide Web Consortium. Its purpose is to deliver the information of the World Wide Web. It also develops rules and guidelines for the Web.

### 34) What is tweening?

It is the process of generating intermediate frames between two images.

It gives the impression that the first image has smoothly evolved into the second one.

It is an important method used in all types of animations.

In CSS3, Transforms (matrix, translate, rotate, scale) module can be used to achieve tweening.

## 7) Which HTML tag is used to display the data in the tabular form?

The **HTML table tag** is used to display data in tabular form (row \* column). It also manages the layout of the page, e.g., header section, navigation bar, body content, footer section. Here is the list of tags used while displaying the data in the tabular form:

Tag	Description
<table>	It defines a table.
<tr>	It defines a row in a table.
<th>	It defines a header cell in a table.
<td>	It defines a cell in a table.
<caption>	It defines the table caption.

<colgroup>	It specifies a group of one or more columns in a table for formatting.
<col>	It is used with <colgroup> element to specify column properties for each column.
<tbody>	It is used to group the body content in a table.
<thead>	It is used to group the header content in a table.
<tfooter>	It is used to group the footer content in a table.

## 10) What is semantic HTML?

Semantic HTML is a coding style. It is the use of HTML markup to reinforce the semantics or meaning of the content. For example: In semantic HTML <b> </b> tag is not used for bold statement as well as <i> </i> tag is used for italic. Instead of these we use <strong></strong> and <em></em> tags.

## 11) What is an image map?

Image map facilitates you to link many different web pages using a single image. It is represented by <map> tag. You can define shapes in images that you want to make part of an image mapping.

## 13) How to create a nested webpage in HTML?

The HTML iframe tag is used to display a nested webpage. In other words, it represents a webpage within a webpage. The HTML <iframe> tag defines an inline frame. For example:

## 22) How to make a picture of a background image of a web page?

To make a picture a background image on a web page, you should put the following tag code after the </head> tag.

1. <body background = "image.gif">

Here, replace the "image.gif" with the name of your image file which you want to display on your web page.

## 23) What are empty elements?

HTML elements with no content are called empty elements. For example: <br>, <hr> etc.

1. `<iframe src="demo_iframe.html" width="200px" height="200px"></iframe>`

## 26) What are the entities in HTML?

The HTML character entities are used as a replacement for reserved characters in HTML. You can also replace characters that are not present on your keyboard by entities. These characters are replaced because some characters are reserved in HTML.

## 27) Why is a URL encoded in HTML?

An URL is encoded to convert non-ASCII characters into a format that can be used over the Internet because a URL is sent over the Internet by using the ASCII character-set only. If a URL contains characters outside the ASCII set, the URL has to be converted. The non-ASCII characters are replaced with a "%" followed by hexadecimal digits.

## 29) What is the canvas element in HTML5?

The <canvas> element is a container that is used to draw graphics on the web page using scripting language like JavaScript. It allows for dynamic and scriptable rendering of 2D shapes and bitmap images. There are several methods in canvas to draw paths, boxes, circles, text and add images. For Example:

1. `<canvas id="myCanvas1" width="300" height="100" style="border:2px solid;">`
2. Your browser does not support the HTML5 canvas tag.
3. `</canvas>`

### 30) What is SVG?

HTML SVG is used to describe the two-dimensional vector and vector/raster graphics. SVG images and their behaviors are defined in XML text files. So as XML files, you can create and edit an SVG image with the text editor. It is mostly used for vector type diagrams like pie charts, 2-Dimensional graphs in an X, Y coordinate system.

1. `<svg width="100" height="100">`
2. `<circle cx="50" cy="50" r="40" stroke="yellow" stroke-width="4" fill="red" />`
3. `</svg>`

### 36) What is the use of figure tag in HTML 5?

The figure tag is used to add a photo in the document on the web page. It is used to handle the group of diagrams, photos, code listing with some embedded content.

1. `<p>`The Taj Mahal is widely recognized as "the jewel of Muslim art in India and one of the universally admired masterpieces of the world's heritage."`</p>`
2. `<figure>`
3. ``
4. `</figure>`

### 37) What is the use of figcaption tag in HTML 5?

The `<figcaption>` element is used to provide a caption to an image. It is an optional tag and can appear before or after the content within the `<figure>` tag. The `<figcaption>` element is used with `<figure>` element and it can be placed as the first or last child of the `<figure>` element.

1. `<figure>`
2. ``
3. `<figcaption>`Fig.1.1 - A front view of the great Taj Mahal in Agra.`</figcaption>`
4. `</figure>`

**42) If I do not put <!DOCTYPE html> will HTML 5 work?**

No, the browser will not be able to identify that it is an HTML document and HTML 5 tags do not function properly..
